NOTE—Horsepower in nearly every case has been determined according to the A. L. A. M. formula, fractions being ignored; whenever a manufacturer gave a hypothetical horsepower the lower figures have been taken. In many cases where ignition is obtained from a magneto, storage batteries are supplied either as a start-up or as part of another complete ignition system; in such cases magneto only is quoted. Wherever a touring and runabout body or limousine and landaulet body are fitted on the same chassis without any alteration of price, touring and limousine only are quoted in each case.

ADVANCES REVEALED BY LICENSED CARS.

Advances have not been confined to the power-plant or its accessories, as it is quite evident that the average designer has been keen to discern possible places for improvement and has taken advantage of them. Though but a few years ago, the time when engineers exclaimed with alarm at the enormous increase made in wheelbase lengths has been forgotten and an extra inch or two, even when added on to what was long thought to be a dangerous excess over the point of safety, no longer excites any comment. With one or two special exceptions such as that of the Franklin, practice in frame design appears to have reached an exceedingly well-defined standard even where general frame design is in question, as the sub-frame is now only seen occasionally.

Naturally the thing that will take the attention of the average visitor is the collection of "sixes," but as in the majority of instances they do not represent special designs, they have not been treated in the usual sequence under the head of advances. One striking exception to this is the new Lozier of this type, while others who will stage sixes are the Apperson, Peerless, Oldsmobile, and Winton. These are all new entrants into this field, while those who showed sixes last year were the Stevens-Duryea, Franklin, and Pierce. The first-named again shows both a "Big" six and a "Little," and this is also true of the Pierce, the smaller

model of this type being a new design in which have been incorporated numerous features of merit.

With the Electrics and Commercial Cars.

Electric vehicle design has always closely followed the carriage makers' standards where lines, construction, and finish are concerned, and the first maker to break away from the latter is the General Vehicle Company, which exhibits a line of pleasure vehicles patterned more after those of the gasoline type than ever before, both where design and finish are concerned. The Baker, Babcock, Pope, and Studebaker companies show full lines of their electric cars, about which there is little that can be said under the head of general tendencies, at any rate, as these remain practically the same throughout where both design and construction are concerned.

Where commercial vehicles are concerned, there is a more representative showing than has been the case formerly. The Packard Company has developed a special type of gasoline-driven truck, and this is also true of the Franklin. Quite the most striking development in this field, however, is the appearance of the Alden Sampson gasoline-electric train. Other exhibits are to be the Champion wagons and the Studebaker, Pope and General Electric commercial vehicles, of which as comprehensive a showing as the Garden has ever housed will be exhibited in the basement.

## SOMETHING ABOUT THE CARS AT THE GARDEN

**ALDEN SAMPSON.**—By far the most striking exhibit to be found in the commercial section of the show is that of the Alden Sampson Manufacturing Company, Pittsfield, Mass. This concern has been closely identified with the automobile industry in this country for the past six years, but the present constitutes the first product to be exhibited for several years. It consists of a special form of tractor, which has been given the title of the Gas-Electric Road Train, from the fact that the motive power is originally supplied by a gasoline motor of the standard type, direct coupled to an electric generator. This furnishes current to the tractor's motors and to two trailers, the motors being mounted on an independent truck. All three carry a load aggregating twenty tons. Both the control and steering are centered on the tractor, making the train easily handled by one man. On the level with full load its speed is six m. p. h.

This firm is also building three and five-ton trucks, in addition to which it will devote attention to the manufacture of pleasure cars.

**Apperson.**—In addition to the standard 50-55-horsepower Apperson touring car, and the well-known "Jack-Rabbit," there is a new Apperson for 1908, rated at 30-35 horsepower, and, to quote the maker's preliminary announcement: "Although this car is offered at a much lower price than that at which any Apperson car has heretofore been sold, this new model will, in every respect, including material, workmanship, style, reliability and low cost of maintenance, come up to the regular standard of Apperson quality." Its specifications are also patterned after those of the standard Apperson type as represented in the other cars of the line, a four-cylinder, 4 3-4 by 5-inch, individual cylinder, vertical, water-cooled motor forming the power plant, while the transmission consists of a three-speed sliding gear of the selective type with final drive by shaft. There will also be included in the Apperson line a six-cylinder 50-55-horsepower touring car along similar lines to those of the four-cylinder car of this power.

**Autocar.**—Improvement of the substantial, conservative order, which is not heralded with much ado at the opening of each new season, has always characterized the Autocar Company, Ardmore, Pa., and this policy has been strictly adhered to in the planning of the 1908 line. Despite the fact that the multi-cylindered car is now on the crest of the wave, the Autocar designers have neither produced a six-cylindered car nor let the demand of the moment undermine their judgment, and have accordingly continued the popular two-cylinder runabout so long associated with the name. This is the only car of its kind in the entire show. Its construction has been standardized to such an extent that any description of its features would be but a repetition of what has gone before, as ever since its inception the design has been retained intact, improvements being confined to detail. The other member of the line is the 30-horsepower Autocar touring type, which is also fitted with runabout and limousine bodies, and the specifications of which are equally familiar to the average American autoist.

**Baker.**—After exhaustive study of the problem, supplemented by a great deal of experimenting, the Baker Motor Vehicle Company, Cleveland, O., will bring out for 1908 a one-ton electric commercial vehicle embodying the results of their extensive experience in the building of electric cars, as well as what they have learned from their past two or three years' study

of commercial vehicle needs. It will be fitted with either an open or a delivery body. Another new Baker is an inside-driven coupé, which is mounted on a standard chassis and is interchangeable with a victoria body, while the line is still further supplemented by the addition of a new brougham. The Baker roadster, which created no little interest when shown for the first time last year, has been improved until its maximum speed is now 40 miles an hour, while its touring radius at a 14-mile speed is practically 100 miles. Numerous detailed improvements have been made in the line as a whole, but nothing of a radical nature.

**Babcock.**—The name Babcock has been synonymous with electric pleasure vehicles ever since it has been connected with the automobile industry, and the makers, the Babcock Electric Carriage Company, Buffalo, N. Y., have done a great deal to enhance the reputation for quiet, easy running, and everyday reliability in all weathers that the electric vehicle has achieved. Five models are listed and will be shown by the New York agents, Wyckoff, Church & Partridge. These are the Model 10, inside-driven coupé; Model 6, Victoria; Model 1, special stanhope; Model 5, long-distance runabout, and a brougham. Models 10 and 6 are practically the same chassis, and the coupé and Victoria bodies are interchangeable. The battery equipment has been divided, and with the motor slung under the center of the body the weight is very evenly distributed. Models 5 and 6 have a maximum speed range of 26 miles an hour and a single-charge radius of 75 miles, the others being slightly less owing to increased weight.

**Buick.**—Complying with its promises of a year ago, the Buick Motor Company, Flint and Jackson, Mich., will reveal at the show their new four-cylinder offering in the shape of a three-seated runabout listed at \$850, of which a large number are to be turned out during the season of 1908. In making additions to the Buick line, cars have been added at either end so to speak, as the new offerings consist of the popular-priced machine just referred to, and a seven-passenger, 40-horsepower touring car, fitted with Bosch magneto, Michelin tires, and other features only to be found on cars of the highest grade, although this newcomer is listed at \$2,550. It is known as Model 5, while the runabout is Model 10. The latter has a standard four-cylinder motor which is practically a replica of the larger size and is rated at 20-25 horsepower, the transmission consisting of a two-speed planetary gear and single-chain drive. The other cars shown are the Model S, two-cylinder, 22-horsepower, the Model F, four-cylinder, 30-horsepower touring, and the roadster on the last-named chassis.

**Corbin.**—In order to be in a position to meet the demands of its customers who favor either type of motor, the Corbin Motor Vehicle Corporation, New Britain, Conn., decided to duplicate the air-cooled cars of this name, which it has made so justly popular, with a second line which should be the same in practically every particular except that the engine is water-cooled. This decision was arrived at early last spring, and the new car is known as Model K. Under the new A. L. A. M. formula for horsepower calculation, it is rated at the anomalous figure of 32.4 horsepower, but will naturally show a great deal more than this, and under previous methods would have had a rating at least fifty per cent. higher. Both cars are equipped with the standard four-cylinder motor evolved by this firm, a high-tension magneto having been adopted for ignition. A conical type of clutch forms the first step in the transmission of the power, being coupled to a three-speed selective gear-set with final drive by shaft to a standard type of floating rear axle, which differs, however, in being encased in a one-piece housing of Cramp's bronze. Roadster, touring, and limousine types are listed.

**Cadillac.**—As has been the case with this car in former years, it is listed in a wider range of types and sizes than probably any other car on the market. In refutation of those who have been so confidently predicting the early demise of the single-cylinder type of car all along, the Cadillac Motor Car Company, Detroit, Mich., show their familiar one-cylinder, 10-horsepower chassis with no less than three different bodies. The first is a two-seated runabout, the second a straight-line four-seated touring type, and the third an inside-driven two-seated coupé. In like manner the four-cylinder 25-horsepower Model G is shown in a similar line of bodies, including runabout, touring and limousine types, while the 30-horsepower Model H, also of the four-cylinder type and well-known through its numerous distinctive features of construction, is listed as a touring car and limousine. The single-cylinder chassis is also listed as a delivery wagon, a body of the usual inclosed type being fitted.

**Columbia.**—The Electric Vehicle Company, Hartford, Conn., furnishes considerable for the technical expert to ponder and study over in the shape of their Columbia gasoline-electric 60-horsepower car, with its simple and extremely smooth-working transmission, which is characterized by its total lack of gears—or, for that matter, any form of mechanical connection. The latter, so to speak, is "floating," in that the bond between the engine and the driving wheels is of the invisible type set up by magnetism, as the field of an electric generator forms the flywheel of the motor, while the armature of the dynamo is solidly attached to the forward end of the propeller shaft. Directly behind the generator, and with its armature also forming a part of the propeller shaft, is an electric motor in which is utilized all the surplus power put into the dynamo by the motor and which appears as electric energy. This provides five forward speeds, any of which may be thrown in or out without the slightest perceptible jerk in the car's speed, control being similar to that used on a street car, but of smaller size. The standard four-cylinder Columbia car is also shown.

**Columbus Electric.**—As is the case with the gasoline car, inclosed types predominate where electric vehicles are concerned, and the Columbus line, which is the product of the automobile department of the Columbus Buggy Company, Columbus, O., is no exception to the rule. In fact, the wholly open vehicle, with no overhead protection, is no longer in demand, as evidenced by the Columbus line, which consists of a Stanhope, No. 1,000, having a 69-inch wheelbase and 30 by 3 1-2 pneumatic tires on wood artillery wheels; a surrey with top having an 89-inch wheelbase and 34 by 4-inch pneumatics on the same type of running gear; a station wagon, No. 1,102, of similar specifications, and an inside-driven coupé, No. 1,002, on the same chassis as the Stanhope, the bodies of Nos. 1,000, 1,001 and 1,002 being interchangeable. Battery weight is distributed by placing half of the cells in front and half in the rear; twenty-four cells are used, and the mileage varies from 50 to 65 miles, according to the size and weight of the car.

**Elmore.**—Numerous improvements mark the two Elmore two-cycle models for 1908, which are made by the Elmore Manufacturing Company, Clyde, O. They are known as Model L, which is the three-cylinder car, and the only one of its kind shown in the Garden, and Model M, the four-cylinder two-cycle car. The well-known Atwater-Kent "spark generator" has been made a feature of both, and the same is true of the new Brown-Lipe type of selective change-speed gear. The pedal brake has been removed from the propeller shaft and an external double-acting brake placed on large hubs mounted on the rear wheels substituted. Speaking of the Elmore ignition, the makers state that they have run their cars 2,000 miles on a single set of 6, six-inch dry cells, with the aid of the Atwater-Kent apparatus. The engines in both models have been refined in numerous details, the pistons have been made much thinner, the connecting rods are now drop-forgings, and the muffler has been improved and made much lighter. Betterments have likewise been made on the other parts of the car, such as the adoption of a new

and improved steering column, new hubs on the wheels, square live axle at differential ends, larger ball bearings in front wheels and similar improvements, which have been made wherever the makers found it possible to do so.

**Franklin.**—"More horsepower" is the Franklin slogan for 1908, and, incidentally, it is well to add that it means more power without a corresponding increase in weight. In bringing this about, the Franklin Automobile Company, Syracuse, N. Y., has evolved an entirely new type of motor. A dome-shaped or spherical combustion chamber has been adopted, together with a very ingeniously worked-out type of concentric valve, thus providing the maximum valve area with the minimum space, this also greatly adding to the cooling ability of the motor by insulating the exhaust valve from the cylinder head, the inlet valve forming the outer of the two valves. Another improvement, which has been in use since early in the present season, is an oil baffle plate in the crank chamber, one of these being placed between the engine base and each cylinder, and having a slot in it for the free movement of the connecting rod, this method placing the oil exactly where it is most needed. The adoption of phosphor bronze cooling flanges is another innovation—in short, the new Type D fairly bristles with improvements and is bound to prove a center of attraction.

**General.**—Quite a radical departure from previous standards of commercial vehicle design in the electric field is to be noted in the models put forth by the General Vehicle Company, Long Island City, New York. All of the 1908 models to be shown by this company have long semi-elliptic springs, with an unusually long wheelbase and low suspension, which at once strikes the observer accustomed to seeing business electric vehicles owing to the change in their appearance which this brings about. The exhibit of pleasure vehicles also reveals a radical departure from previous practice, the landaulet, victoria-phaeton, and runabout to be staged, all being built upon pressed steel frames with long semi-elliptic suspension, single motor with differential countershaft, silent chain transmission, and roller bearings. They are also finished in attractive colors in place of the old conservative coach colors so long a feature of such cars. The landaulet is patterned after gasoline car practice to some extent in that the battery is placed under a bonnet forward.

**Haynes.**—Three distinct types of cars go to make up the Haynes 1908 line, and all are to be included in the exhibit of the makers, the Haynes Automobile Company, Kokomo, Ind. The Haynes is a car of such long standing that it is naturally one of the last in the show on which to look for radical changes of any kind, so that on no one of the three types, rated at 30, 45 and 60 horsepower respectively, is anything of the kind revealed. The 45-horsepower car is a newcomer to the Haynes family, and has been christened Model W; it has been brought out with a view to supplying a lightweight car of ample power and seating capacity, and it has the experience of a great many years of automobile building back of it. It goes without saying that the object of its designers and builders has been achieved in no uncertain manner, particularly as the latter have the entire creation of the car in their hands, making every part from the raw material in their own factory. The motor is of the standard Haynes types and double ignition, using a magneto and accumulators is specified.

**Hewitt.**—Cars of this make, which are the product of the Hewitt Motor Car Company, New York City, occupy an anomalous position by reason of the fact that they are shown in two extremes where the number of cylinders is concerned, as the Hewitt runabout and town car is equipped with a single-cylinder motor, while the Hewitt touring car is quite at the other end of the line with an eight-cylinder motor, and the only one of its kind to be shown. The latter is of the Renault type, with the cylinders placed at a 90-degree angle, the design being very well worked out, as described in these columns at the time of the car's appearance. This company also devotes considerable of its attention to the production of gasoline-driven

commercial vehicles, from a single-cylinder delivery wagon up to a ten-ton truck, a planetary type of change-speed gear of special design, patented by Mr. Hewitt, being a distinguishing feature of all of them.

**Knox.**—"Wishing to enjoy the patronage of those who prefer water-cooling, and, at the same time, to allow those preferring water to enjoy the many other desirable and important features of the Knox construction, we have brought out and are now prepared with our Model L, water-cooled car," says the Knox Automobile Company, Springfield, Mass., in one of its preliminary announcements regarding the 1908 line. But except for the fact that its motor is water-cooled, the new Model L is a typical Knox product from bonnet to rear wheels. The motor itself is of far more than passing interest. At first sight it appears to be merely a water-cooled replica of the well-known air-cooling type, but closer inspection reveals the fact that the cylinders are made with separable heads, the valves being in the latter in accordance with Knox practice. This construction is novel and embodies a number of advantages that will be obvious. The regular 30-horsepower Model H air-cooled touring car is continued practically the same and will be pushed with as much energy as ever, the Knox company believing in doing all it can in both lines.

**Locomobile.**—Steady-going conservatism of the type that is slow to forsake a good thing for something uncertain, but that is always quick to appreciate and take advantage of real improvement, has always marked the design of the Locomobile, so that when its makers, the Locomobile Company of America, Bridgeport, Conn., announce that they have made "improvements" in a new model, the word is meant in its full significance and does not imply that another brand of ignition cable has been adopted, or something equally trivial, but that genuine advances have been made. Chief among those to be found in the 1908 offering are the adoption of a four-speed selective type of change-speed gear for the Type E, 20-horsepower car. This type is also listed with a special form of removable tonneau interchangeable with a rear deck, no tools being required to make the change. A new feature of motor construction is the use of a large bronze plate carrying the water-circulating connection and covering an opening in the top of the jacket, besides which there are other changes of merit.

**Lozier.**—The three Lozier models comprising the 1908 line of the Lozier Motor Company, New York, will constitute this firm's exhibit. The new Type H, shaft-driven, ball bearing Lozier of 45 horsepower is represented by a stripped chassis and a seven-passenger touring car, and as it is not only the latest addition to the Lozier line, but likewise one which represents an advanced form of design and construction, it will naturally come in for the major share of attention at this exhibit. Although in this respect it must share the honors with the new 50-horsepower, six-cylinder, shaft-driven Lozier, this also forms an entirely new addition to Lozier line, so that the latter now offers quite a range of models, beginning with the 40-horsepower chain-driven type, which is practically the same design and construction as last year, and ending with the six-cylinder model just mentioned. Nickel-steel and chrome-nickel alloy steels are extensively used in the construction of the entire Lozier product for axles, frames, shafts, gears, and the like, while annular ball bearings are used wherever possible.

**Matheson.**—But one type of chassis comprises the line of the Matheson Motor Car Company, Wilkes-Barre, Pa., which is marketed through the Palmer & Singer Manufacturing Company, New York. This is equipped with a 45-50-horsepower motor of distinctive type, embodying many exclusive features, such as the single superimposed camshaft, oppositely disposed valves in the head, the design of the valve-operating mechanism, low-tension ignition, using Bosch magneto, and others which have characterized it since its inception, improvement in the meantime having been centered upon a refinement of the design rather than radical change. It is shown as a three-passenger

runabout, and a seven-passenger touring car, limousine, or landulet. Transmission is by multiple-disc clutch, with a selective type of change-speed gear and double side-chain final drive, the wheelbase being 128 inches in every case and the weights 3,200 pounds for the runabout, 3,400 for the touring type, and 3,600 for the inclosed types.

**Northern.**—Adherence to ideals adopted long before the trend of motor design and construction had settled down to the well-defined standards which now characterize them has always characterized the product of the Northern Motor Car Company, of Detroit and Port Huron, Mich., and the fact that the designers have not had to depart from their early conceptions as the result of this settling process speaks for itself. For 1908 the two-cylinder shaft-driven car with the motor placed transversely forward and at an angle to align the crankshaft with the cardan shaft, and which was one of the first of its kind, is listed in three types. It is known as Model C and is rated at 24 horsepower, being shown as a three-seated roadster, a five-passenger tonneau car, and as a seven-passenger limousine. It is equipped with the metal to metal clutch and planetary change-speed gear that have always distinguished it. The other member of the line is the Model L, 40-horsepower, four-cylinder car, which is shown in both runabout and touring types.

**Oldsmobile.**—A car of this make forms one of the numerous coterie of six-cylinder models to be unveiled at the show, and its specifications are accordingly of more than passing interest. It is known as Model Z and is a 60-horsepower, seven-passenger car, although under the new A. L. A. M. formula its rating is but 48 horsepower, the cylinder dimensions being 4 1-2-inch bore by 4 3-4-inch stroke. The cylinders are cast in pairs and are water-cooled, the radiator being of the vertical tubular fin type—in fact, its distinguishing characteristics are those that have become familiar on the four-cylinder model, except that various modifications and improvements have been made, such as the equipment of a dual system of ignition, using a Bosch high-tension magneto on the running side. The 1908 touring car is known as Model M, and its wheelbase is 112 1-2 inches as compared with 130 inches on the six-cylinder type. Both are fitted with an internal cone clutch with cork inserts, three-speed selective gear and shaft-drive, and semi-elliptic suspension.

**Packard.**—The forerunner of all the "Thirties" shown by the Packard Motor Car Company, Detroit, Mich., is distinctively Packard in every line of its make-up, and those who are familiar with American cars will realize the significance of the expression. The groundwork of the design is essentially the same as it has been ever since the builders have been devoting their attention to a four-cylinder car. From that time on, the entire process has been one of development, and in the latter so many distinguishing features have been evolved that a Packard can almost be identified in the dark. The standard motor, with its special type of water-jacketed carbureter and hydraulic governor, the expanding band clutch, and the progressive type of sliding gear mounted on the rear axle under the same housing as the bevel-drive and differential are all familiar features which have been constantly improved in detail and incorporated in each successive Packard. Simply to say that it's a Packard suffices to describe it.

**Peerless.**—As compared with previous models the Peerless cars for 1908 are characterized by few changes, the principal improvements consisting of an increased wheelbase, seven-passenger body, pacing of front axle farther forward, the adoption of 36-inch wheels, flat spring suspension, and a duplicate system of ignition employing a high-tension magneto on the running side, so that, to quote the makers, the Peerless Motor Car Company, Cleveland, O.: "The Peerless cars for the season of 1908 are higher-powered, larger, roomier, and more comfortable in riding qualities." Three standard types will be made, respectively known as Model 15, Model 18, and Model 20—the last named being a six-cylinder type that will not make its appearance on the market until after the first of the year. The first-named is a 45-horsepower, seven-passenger car with a 5 1-4 by 5 3-4 horsepower

motor, the cylinders being cast in pairs as formerly. The wheelbase is 119 inches and the car is listed either as a touring or roadster type. The mainstay of the line, however, will be the Model 18, which is a 30-horsepower car with a 4 7-8 by 5 1-2 inch motor, other features conforming to standard Peerless practise.

**Pierce-Arrow.**—Four models comprise the 1908 line of the Pierce factory, and the George N. Pierce Company, Buffalo, N. Y., state in their preliminary announcement that special alloy steels have been made a feature of their entire output, being used extensively wherever desirable. The cars listed are a 30-horsepower, 4-cylinder model, with a 4 1-4 by 4 3-4-inch motor; a 40-horsepower, 4-cylinder model with a 5 by 5 1-2-inch motor, and two 6-cylinder cars rated at 40 and 60-horsepower respectively, the engine dimensions of which are the same as those of the two 4-cylinder types just given. In all these models the sub-frame has been dispensed with, the main frame being constructed of chrome-nickel pressed steel of channel section, with four pressed steel transverse members, the forward one of which forms the radiator support. The power plant is directly supported on two I-beam cross girders in place of casting extension arms on the aluminum crankcase, the material of these extra cross pieces having a tensile strength of 65,000 pounds to the square inch.

**Pope-Hartford.**—As the center piece of the exhibit made by the Pope Manufacturing Company, Hartford, Conn., there will be a Pope-Hartford car with complete equipment, giving an idea of the usual accessories employed on a car of its grade, such as a speedometer, odometer, clock, searchlight, tire irons, wind shield, top, magneto, and the like. This is the new Model M Pope-Hartford touring car for 1908, which, with a few detailed exceptions, follows the lines of this year's Pope-Hartford, that proved itself a success in no uncertain manner. There is a Pope-Hartford of the same model to be included in the show with the regular selling equipment, other models staged being a runabout and a limousine, the former shown with a double rumble seat. The Pope-Tribune line will be shown in connection with the Pope-Hartford, a 20-horsepower touring car and 20-horsepower runabout on the same chassis being shown. The runabout is to be shown with complete equipment, including top.

**Pope-Toledo.**—A 50-horsepower touring car, officially known as Type XVII, and a touring runabout on the same chassis constitute the Pope-Toledo line for 1908, and in bringing these out for the coming season the Pope Motor Car Company, Toledo, O., has continued the special design of motor and chassis which was brought out last year. The power plant is of the overhead valve type, but differs considerably from others of this class in that the advantages of oppositely disposed valves have all been retained without the necessity of duplicating the camshafts. Large walking beams are employed, actuated at one end by a pushrod from the single camshaft. The D. W. F. annular ball bearings are largely used in the motor. The radiator is the familiar Pope "planatic" type of their own make. A multiple-disk clutch and a four-speed selective type of change-speed gear, both in the same housing, constitute the main essentials of the transmission, final drive being by means of double side chains. Both wheel and transmission bearings are all of the D. W. F. annular type. The tire equipment is 36 by 4 front and 36 by 4 1-2 inches rear.

**Pope-Waverley.**—Balance, trimness and proportion are the distinguishing features of the Model 71 Pope-Waverley electric runabout, which the designers of the Pope Motor Car Company, Indianapolis, Ind., have changed considerably since last year. The old style box patent body has been done away with, and the battery distribution with its housing has been so effected that the forward and rear projections are well proportioned and give the car an attractive appearance of trimly balanced compactness which is best described as "an air of jauntiness," if such an expression may be applied to something purely mechanical. A closely folding leather buggy type completes the

car's external fitting. A victoria-phaeton with coupé top is another new Pope-Waverley model which was brought out for the first time last year and has been considerably improved since where the matter of body lines are concerned, numerous small conveniences having been added so that this model leaves nothing to be desired.

**Royal Tourist.**—Numerous improvements mark the 1908 line of the Royal Tourist, made by the Royal Motor Car Company, Cleveland, O., in addition to which two new cars have been included, one of them being a four-cylinder, 60-horsepower type, and the other a six-cylinder car of the same power. There have been a few minor changes in the motor, but, in the main, the power plant is of identically the same type as has always formed a distinguishing feature of the Royal for a number of years past. Where the chassis is concerned, however, the suspension has been altered to conform to the three-point type with transverse spring in the rear, or half-platform. Wheel sizes have also been increased from 34 to 36 inches. The showing will consist of a polished chassis, standard seven-passenger touring car and a fully equipped limousine.

**Selden.**—The new Selden cars, which are the product of the Selden Motor Vehicle Company, Rochester, N. Y., make their début at the present Garden show, and, in view of the name they bear, their specifications will be a matter of unusual interest to the autoist. Those who have confidently anticipated anything of a revolutionary or radically different nature from that recognized by standard practise will be disappointed, as the design of the car is lacking in either. It is shown in two distinctive models, the smaller of which is rated at 25-28-horsepower, and will be known as the Selden "25." It is equipped with a four-cylinder, water-cooled motor having high-tension ignition, cone clutch, and three-speed selective type of change-speed gear and shaft-drive. On a 109-inch wheelbase it tips the scales at 1,850 pounds as a touring car or runabout, and at 2,000 pounds as either a limousine or landaulet. The Selden "45" is the larger car, and is rated at 45-60 horsepower. With the exception of dual ignition, using a high-tension Bosch magneto, and a four-speed, selective gear set, the design is practically the same throughout, closely conforming to highest standard practise.

**Stearns.**—There will be a Stearns "30" and a Stearns "45" for 1908, or rather "there are," for both these models have been completed some time since by F. B. Stearns & Company, Cleveland, O., and will be staged at the Garden next Saturday. Though nominally of these low powers, even under the new A. L. A. M. rating, which experience has shown to be unusually conservative, they are credited with 46.22 and 69.3 horsepower, so that under old methods their rating would have been nearer 60 and 90 horsepower. The former is a four-cylinder type, while the latter is the six-cylinder representative of the Stearns line for the coming season. In the main, the same standards of design and construction have been adhered to throughout in both, an internal-expanding type of clutch with selective change-speed gear and double side-chain drive being employed. High-tension ignition by magneto and accumulators is used in both cases. The wheelbase of the smaller car is 120 inches, and the larger 128 inches.

**Stevens-Duryea.**—As the builders of both four and six-cylinder cars in a number of types, the line of the Stevens-Duryea Company, Chicopee Falls, Mass., will be one of the most complete of its kind in the Garden. Both the "Light Six" or Model U, and the "Big Six," otherwise Model S, are still the most prominent representatives of Stevens-Duryea design and construction, while the popular small car of the four-cylinder type, known as Model R, has been retained, and a newcomer, also of the four-cylinder type and which has been christened as Model X, has been added. Touring and inclosed types are listed in five and seven-passenger bodies, the features of construction being those favored by the designers of this firm for some time past, *i. e.*, multiple disk clutch, sliding change-speed gear and shaft drive. A magneto is a feature of the new Model X, which

in other respects conforms to the same practise, but has a longer wheelbase than the other cars, measuring 124 inches, while even the "Big Six's" dimensions on the ground are only 122 inches, which is moderate for a car of its power and size.

**Studebaker.**—Two standard types of chassis will be built under the aegis of the Studebaker name, by the Studebaker Automobile Company, South Bend, Ind., for the coming season, and under the new formula adopted by the Licensed Association they have been given the somewhat peculiar horsepower ratings of 27.2 and 36.1 horsepower, quite in contrast to the previous loose designations that placed the output of a motor anywhere within five or ten horsepower of what the designer thought it was. The smaller car is known as Model H, either as a runabout or limousine, and as Model B, as a touring car, while the larger car is entitled Model A, and at present is only listed in the touring type, having a five-passenger body. The most noticeable difference between the two is the fact that the smaller is fitted with a progressive type of change-speed gear, while the latter is equipped with a selective type, all being shaft-driven. Low-tension ignition is one of the distinctive features. The complete Studebaker line of electrics is also shown.

**Thomas Flyers.**—The exhibit of the E. R. Thomas Motor Company, Buffalo, N. Y., will provide one of the chief attractions of the new season's models and it goes without saying that it will form a center of interest at the Garden. This is the new Thomas cab or town car. In every feature it bears the imprint of an overseas' design, and the fact that those same features represent marked advances of their kind lends them additional interest. Following the initiative set by several French makers, the four-cylinder engine has been made in a single simple casting, this tending greatly to make it much more compact, this being one of the essentials most desired in the power plant of a car intended solely for city use. To the same end the forward part of the frame has been narrowed to a much greater extent than usual in order to have an extra amount of space between it and the front wheels, thus obtaining a particularly small turning radius so that these cars will be able to get around in narrow streets without reversing. Another of their features that will attract unusual interest is the elimination of the pump, thermo-siphon having been adopted.

**Thomas Detroit.**—In line with the policy adopted by the Detroit factory of the E. R. Thomas Motor Company, of Buffalo, N. Y., at the outset, this end of the Thomas interests will devote its entire attention to the production of a single chassis for 1908 as it did during the present season. Its rating remains the same as that which gave it a distinctive title when first brought out, i.e., 40 horsepower, though its appellation has been altered to that of Thomas Detroit, in order to better distinguish it from the product of the Buffalo works. The same type of power-plant, in fact practically the same lines throughout, characterize the new model as did its predecessor. The cylinders are cast in pairs with liberal water-jackets, the valves, spark plugs, carbureter, circulating pump and magneto all being placed on one side. The crankshaft bearings are of liberal dimensions and are of special alloy. All the timing gears, magneto and the oil and water pump-driving gears are placed in a special oil-tight housing. Ignition is by high-tension magneto and dry cells, the latter acting solely as a reserve. It is shown in both touring and runabout types.

**Waltham.**—One of the striking features of the Waltham-Orient line for 1908 will be a 14-16-horsepower, two-cylinder chassis, which will be shown by the makers, the Waltham Manufacturing Company, Waltham, Mass., in a number of styles. It will be equipped as a delivery wagon, as a runabout, and also in the latter type with detachable tonneau and rear deck, making it convertible from one to the other. Some of the remaining members of the line are the 8-horsepower, air-cooled runabout, which has undergone considerable improvement and change in appearance since the former model, and the four-cylinder 20-horsepower, air-cooled chassis, which will be shown in both touring and runabout types. One of the chief features of the

Waltham chassis, particularly the water-cooled type referred to above, is the employment of a unit type of power plant and transmission which can be detached from the car in about thirty minutes; it is bolted to a subframe and everything can be removed intact. There are likewise a number of detailed improvements on the various chassis, which in some instances are apparent at a glance, while in others they do not stand out prominently, though a great deal of attention has been paid to detail.

**Walter.**—In addition to the standard seven-passenger touring car of 40 horsepower that it has built for several years past, the Walter Automobile Company, Trenton, N. J., has added a 30-horsepower model, on which the motor is of somewhat different design. In place of the overhead rocker-arm valve mechanism which has distinguished former models, this is made with a single camshaft operating the valves by the direct thrust method, all being placed on the same side in an outboard valve chamber on each pair of cylinders. This new car will be shown in the shape of a landaulet, while two 40-horsepower types will be shown with touring and runabout bodies, and will be equipped with the same style of motor as the landaulet. The exhibit will be completed by a 40-horsepower limousine which will have the former style of power plant. Considerable attention has been paid to brake design, and the makers claim to have effected great improvements in this essential.

**White.**—In accordance with its policy in former years, The White Company, Cleveland, O., which is again showing with the licensed cars, will display one of the most complete lines of cars to be seen in the Garden. Both the new models, K and L, will be staged with a number of different types of bodies. The Model K is a 30-horsepower machine patterned closely after the lines of the Model G of the present season; it is shown as a touring car, limousine, landaulet, and runabout. The smaller car, or Model L, is the 20-horsepower car for 1908, and it is shown in touring, limousine, and landaulet types. The most striking change is to be found in the larger car, which is fitted with a straight-line body, this being the first of its kind ever presented by The White Company. The wheelbase of this car has been increased to 122 inches, while that of the smaller car remains at 116 inches, and the runabout's dimensions is 105 inches. The motor of the smaller car is now mounted on an aluminum pan, inclosing it entirely from beneath and thus eliminating the subframe. Numerous other detailed mechanical improvements have been made in the power plants of both cars, and, though small in themselves, in the aggregate they serve to give some idea of the painstaking attention to detail continually being devoted to the improvement of the White by its designers.

**Winton.**—"Six-Teen-Six," which is a title expressive of the fact that this is the sixteenth consecutive model turned out by the Winton factory, and is of the six-cylinder type, represents the sole bearer of the Winton standard that the Winton Motor Carriage Company, Cleveland, O., will devote its entire efforts to during the coming year. Though of the six-cylinder type, no attempt has been made to build an extremely high-powered car, but the conservatism that has always marked the Winton line is adhered to, the rating being 40 horsepower. The car embodies numerous features of merit, probably the first of which to strike even the inexperienced eye being the valve mechanism covers and the special self-starting device. The latter works on the compressed-air principle, and, in view of the number of parts necessarily entailed in the successful design of such a device, this has been made exceedingly simple and compact. The capacity of the tank is sufficient to turn the motor over a number of turns, compression being taken only on the firing stroke of the first cylinder. This is accomplished by the use of a check-valve which does not yield to the force of the compression stroke as the pressure of the latter is not sufficient to move it. The distributing valve is simple and efficient and the chief advantage of the starter as a whole is its simplicity and ease of operation, it not being necessary to go through a number of stunts, beside which the process of using the crank would be a simple thing.

AT ST. LOUIS JUST BEFORE THE SKY VESSELS LEFT THEIR MOORINGS—ARRANGEMENTS WERE THOROUGH AND WELL CARRIED OUT.

FROM France the James Gordon Bennett aeronautical cup came to America; from America it will go to Germany, unless, as is exceedingly improbable, it should be found on final measurement that France has a longer mileage than her rival from across the Rhine. Nine balloons, representing America, Germany, France, and England, lined up at St. Louis, Monday, October 21, for the start in the second race for the Bennett trophy, and the first international balloon race ever held in this country.

Promptly at 4 o'clock P.M., in the presence of a crowd which the conservative estimated at 300,000 and which the enthusiastic carried forward to half a million, Oscar Erbsloeh, in the *Pommern*, one of last year's starters from Paris, ascended lazily into the air to the tune of "Die Wacht am Rhein" and the cheers from thousands of throats. Major Henry B. Hersey, in the *United States*, the only American-built balloon in the race, went into the unknown five minutes later. Major Hersey was Lieutenant Lahm's companion last year, when the young American won the cup in a flight of 415 miles from Paris to the north of England. An attack of typhoid fever when on military service in France had prevented Lieutenant Lahm from competing in or even witnessing the start of the second aeronautical contest.

WINNER ERBSLOEH.

Alfred Leblanc doffed his hat and swung it around excitedly as the "Marseillaise" pealed forth in honor of himself and the *Isle de France*. On the tick of the clock the *Dusseldorf*, with Herr Abercron in charge, joined the sky brigade, followed by *Lotus II*, the solitary Britisher, manned by Griffith Brewer and Claude Brabazon. Captain C. De F. Chandler and J. C. McCoy, in the big balloon *America*, received a tremendous ovation, especially

from the officers and men from the barracks and the Signal Corps. René Gasnier and Charles Levée in the *Anjou*, from Paris; Paul Meckel in the little *Abercron*, from Germany; then the *St. Louis*, piloted by Alan R. Hawley and Augustus Pope, closed the march. Forty minutes had been occupied in starting the nine big balloons, each one rising into the air at its appointed time without any delay or the slightest mishap.

Inflation of the nine gas bags had begun at 8 o'clock, with such a strong pressure and such an excellent quality of gas that before 11 o'clock the supply had to be shut down and was not turned on again until 2 o'clock. At each balloon twenty-one soldiers in charge of a United States Signal Corps man, and a number of expert workmen, watched the inflation, arranged the netting, attached the sand bags, climbed into the netting to fix national flags and streamers, and gave all necessary attention for the start. At the outer edge of the enclosure troops handled the crowd in an excellent manner, the whole proceedings being a credit to the Aero Club of America and a surprise to the foreigners, few of whom had thought such a high standard of efficiency possible at America's first international aeronautical race.

Oscar Erbsloeh, who came down near Asbury Park, N. J., so near to the sea that further flight was impossible, briefly tells the story of how he won the second contest for the international aeronautical cup. "We started promptly at 4 o'clock, rose to a height of 5,000 feet and there found a current carrying us eastward. All night we remained at this altitude, sailing east, and passing over a great many rivers and cities. On Tuesday morning we rose to a height of 6,500 feet and felt very comfortable. Owing to our

"POMMERN" OF GERMANY, THE CUP WINNER

"UNITED STATES," THE CUP WINNER OF 1906

PRES. C. F. BISHOP GIVING INSTRUCTIONS. STARTER C. J. GLIDDEN AND COLGATE HOYT. PLACING THE FLAG ON THE "UNITED STATES."

good charts we nearly always knew where we were. Only once had we to come near earth to ask for information, and that was at Fort Washington, in Ohio. We continued our journey until early on Thursday morning the city of Philadelphia appeared in sight. Wishing to get a current which would carry us into Massachusetts, we lowered to 300 feet, then rose to 10,000 feet, but failed to find any other current but that which took us east, so resolved to descend at the mouth of the Shark river. We decided to go as close to the ocean as possible and finally made a successful descent in an open lot at Asbury Park. We had covered 876 miles."

Alfred Leblanc and E. W. Mix, the former a Parisian technical expert, and the latter a native of Ohio, came second, only six miles behind the German team, by ascending at Herbertsville, N. J. The *Isle de France* crew declare that had their guide rope not caught in a tree at Orange county, N. J., they would have gone straight on and descended at the water's edge. Anxious to ascertain exactly their position in the race, they have asked that the flight be measured. This will be done, awards being held until after this official announcement, expected in thirty days.

Von Abercron, in the *Dusseldorf*, secured third prize by a de-

scent at Dover, Del., approximately 780 miles. The *America* and the *St. Louis* took fourth and fifth places, with 720 and 710 miles, both descending in Maryland. Meckel's *Abercron* and René Gasnier's *Anjou* both drifted down to Virginia, the German having 700 miles and the Frenchman 680. Major Hersey's *United States* struck out an independent course and after a journey of 650 miles came to earth at Calcedonia, Ontario. *Lotus II*, the English representative, found a landing at Sabina, O., after completing a journey of 375 miles.

#### Beachy Wins the Dirigible Prize.

Quite as much interest was displayed in the three-mile race for dirigible balloons on the last day of the St. Louis aeronautical carnival as had been manifested in the start for the Bennett cup. There were four contestants and three heats, but only in the last was there any sharp contest. In the final heat Lincoln Beachy, of Toledo, O., drove his dirigible balloon *Beachy* round the three-mile course, part of the distance against a head wind, in 4:40, descending on the very spot from which he had started. Jack Dallas, of Texas, had a record of 6:10; Captain Thomas S. Baldwin, of New York, had the next best time in the *Arrow*, in 7:05.

LINCOLN BEACHY, OF TOLEDO, O., AND HIS DIRIGIBLE BALLOON "BEACHY," WINNER OF THE EVENT FOR STEERABLE AIRSHIPS.

## BATTLE OF THE CYLINDERS: SIX VERSUS FOUR

By F. B. STEARNS.

WHILE a few of the automobile manufacturers of the country are to-day building the six-cylinder car, there is grave doubt in the minds of the leading designers and engineers as to whether this new demand for cars of enormous power is not but a passing craze, and many of the highest grade manufacturers will have nothing to do with sixes. At this time many manufacturers who are building six cylinders are doing so against their will, not because they favor such a type, but because they have been forced into it. Take them large and small, here, there, and everywhere, and without exception the leaders of the American automobile industry are continuing their four-cylinder cars, building as many as usual, and constructing but a small number of sixes because they have been forced into it.

The claim of some manufacturers, who are strongly in favor of six cylinders, is the fact that their present six-cylinder cars run smoother and easier than their fours—in technical terms, the torque is much more continuous. "In our four-cylinder cars," say these manufacturers, "we were utterly unable to overcome this difficulty, but the addition of two more cylinders obviates this entirely."

This is very plausible on the face of the matter, but how different are the real facts. The best four-cylinder cars made to-day, and by the word "best" I mean the very few who have no superiors, run as smoothly as any six-cylinder cars, with the motor running at anything over 200 revolutions. Above that it is utterly impossible to notice any difference.

While the Stearns Company have had wonderful success with their six-cylinder car, as is evinced by its records in races, hill-climbs, etc., at the same time we are firm believers in the four-cylinder type of car, for many years of experimenting have taught us that the four-cylinder motor, conscientiously made by skilled workmen under expert supervision, is good enough for any car. This does not apply to those manufacturers who have had more or less trouble with their fours, and at last thankfully to the sixes as a way out of their difficulty, but to the best manufacturers in the business.

The basic argument in favor of the six cylinder is, as noted above, the continuous torque—but let us carefully dissect this argument for a moment. A six-cylinder motor geared, say 2 to 1, delivers 12 impulses to the rear axle for every revolution of the wheels. Acting on precisely the same principle, a single cylinder motor geared 12 to 1 will also deliver 12 impulses to the axle for every revolution, and the forward movement of the car is just as smooth as though six cylinders were employed.

It has been claimed that six cylinders of given size will develop 50 per cent. more power than four cylinders of equal dimensions, all other things being equal. But is this really the case? I think not.

Years of experimenting have shown us that with all other things equal the addition of two more cylinders does *not* produce 50 per cent. more power. In fact, a much smaller percentage than that was all that could be noticed after over a year of expert testing. While the same result may not have been achieved by a few other makers, years of conscientious study and application to this problem have conclusively proven the above results, due almost entirely to the high state of efficiency at which our four-cylinder motors have arrived.

The principal difficulties with the six cylinder, which no one can deny, are that it requires 50 per cent. more mechanical parts, 50 per cent. more ignition apparatus, 50 per cent. more gas apparatus, has 50 per cent. more valves to grind, has 50 per cent. more weight, and requires 50 per cent. more radiating surface than a four-cylinder motor of equal power, and consequently requires 50 per cent. more care, and last, but not least, 50 per cent. more repair bills.

The statement is continually made that gasoline engines as they now have been perfected cause practically no trouble, and that by putting in 50 per cent. more parts it means no more trouble because there is no trouble at all. This may be true when the car is new, and all the six-cylinder cars in this country are in their first and second years, but what about them when the time *does* come to have the car overhauled? There is no question but that the repair man's bills will be 50 per cent. greater because there are 50 per cent. more parts to look after and re-adjust and refit.

Another difficulty about the six cylinder is the enormous length of hood that the motor occupies. The result is that in order to get a wheelbase under 135 inches the constructor must place a large portion of the motor directly over the front axle, which necessarily makes hard steering, is hard on tires and springs, and is extremely hard on the delicate adjustments in the motor. The aim of all designers is to get the passengers and mechanism between the axles, and this has become standard motor car construction in the best cars the world over. Except with an excessively long wheelbase this is impossible with the six cylinder, and the addition of a long wheelbase makes the car so long that it is impossible to handle it readily in traffic or even to turn around in the wide streets.

Because the principal cost of a motor car is in the skill required to machine, assemble, and adjust the delicate parts of the motor mechanism, the cost of a six-cylinder car must necessarily be greater in order to produce an equal grade of workmanship with the four-cylinder car. The carburetion difficulties increase because there are two cylinders taking in gas at the same time, and great care must be used to distribute this evenly to all cylinders. Think of an ordinary chauffeur attempting to grind in 12 valves and to time a double system of ignition, or to adjust the valve timing! This means that when the six-cylinder motor does get into trouble, which unfortunately the best motors of any kind are apt to do, it will require more skilled experts to properly adjust a six-cylinder motor than a four.

Throughout the world it is almost invariably the case that racing machines are four cylinders. We ourselves build six-cylinder cars for one purpose, and that is to give the speed and power that a few drivers demand. In other words, if an automobile owner is not satisfied with 60-70 brake horsepower, which our four-cylinder motor gives, and wants something between 90 and 100 horsepower for speed contests, special hill-climbs, etc., the easiest way to give him this is to build a six-cylinder motor. This is absolutely the only use we can see for a six-cylinder motor—that is, extreme power—and for this extreme high power the six-cylinder motor is practically suited.

It is probably not out of place to state that we claim to obtain in our four-cylinder motor the gradual and even application of torque that is talked so much about in the six. This we accomplish by means of a superior carbureter, which we have developed after ten years of constant experimenting to get a perfect gas-making apparatus.

We can best illustrate this by comparing our perfected double carbureter—which turns raw gasoline with a mixture of air into a constant gas—to a steam boiler and steam engine. The supply of gas is always constant, no matter what speed, and by opening the throttle the amount of gas can be so regulated as to get a range of power from one to between 60 and 70 brake horsepower by a simple manipulation of the throttle. The result obtained is equivalent to a constant supply of steam being utilized in a four-cylinder steam engine.

Why, then, is it necessary to use six cylinders if the torque in a four is practically constant, the supply of gas being even and steady at all speeds?

### FOREIGN.

#### Shows.

Nov. 11-23.....	London, Olympia Motor Show.
Nov. 12-Dec. 1..	Paris, Exposition Decennale de l'Automobile, Grand Palals, Esplanade des Invalides, Automobile Club of France.
Nov. 22-30.....	London, Agricultural Hall, Stanley Show.
Dec. 5-22.....	Berlin, Germany, Automobile Show.
Dec. 21-Jan. 2..	Brussels, Show, Palace of the Cinquantenaire.
Jan.18-Feb.2,'08	Turlin, Italy, Fifth International Automobile Exhibition, Palace of Fine Arts, Valentino Park, Automobile Club of Turlin.
Mar. 21-28.....	London, Agricultural Hall, Cordingley's Show.

#### Races, Hill-Climbs, Etc.

Nov. 1-15.....	France, Volturctte Contest near Paris.
May 16, 1908....	Sicily, Targa Florio, Automobile Club of Italy.
June 20-July 5..	Grand Prix, Dieppe Circuit, Automobile Club of France. (Exact date to be announced.)
July 14, 1908...	Paris to London, Aerial Race.
August, 1908...	France, Coupe de la Presse, Automobile Club of France. (Exact date to be announced.)

NIGHT SCENE IN GRAND CENTRAL PALACE, WHERE PHOTOGRAPHY WAS ACCOMPLISHED WITH DIFFICULTY.

THE A. C. A.-A. M. C. M. A. combination to-night closed its third successful show—an exhibition held too early, in the opinion of some, and even too late, according to the ideas of others. Unquestionably there is going to be more or less revision of the show problem, for, candidly speaking, it doesn't seem to fill quite the necessities of the industry as at present developed. But the Grand Central Palace show has been beneficial to the industry as a whole, and while the volume of business transacted did not exceed that of former years, for reasons which are apparent and varied, a balancing of expenditures and receipts will show a profit to the greater number of Grand Central Palace exhibitors. In some instances it meant little more than the introduction of a new name, which must become better known before its possessors realize appreciably upon their investments.

In the buying of automobiles, it should be kept in mind, the public approaches the proposition with more carefulness than was the case a year or more back, when anything that moved under its own power seemed to attract at least a limited number of buyers. But the buyer of to-day is inclined to use greater discrimination, and it has become a case of "show me," convincingly and even economically. Recognizing this condition of affairs, the experienced maker is prepared to meet the revised requirements. The hurrah business is being disregarded, for it doesn't sell cars any more.

Doubtless the most noticeable feature of the Palace

show, to the seasoned rounder who has taken them all in ever since there has been such a thing as an automobile show, was the absence of this hurrah business and the quiet air of dignity that characterized the thing as a whole. There was entirely lacking that feverish bustle and haste that was long an ear-mark of the Garden show in its earlier years and which was transferred in all its virility to the first holding of a similar affair by the independent makers. It took the Garden exhibitors three or four years to wear off that air of extreme activity which, in the last analysis, was only a feverish pretense of doing a tremendous volume of business, and for the show as a whole to acquire an atmosphere of dignified reserve quite in keeping with the character of the product. It seems only fitting that the business of selling automobiles should be placed on a somewhat higher plane than that of developing a real estate boom section in which lots are disposed of on the installment plan, but the process was somewhat akin to this in the early days. Every maker in the show had "disposed of his entire product for the coming year"—long before he got there, in fact—and his presence was merely

ANOTHER VIEW IN THE PALACE, WHICH COULD BE IMPROVED UPON FOR EXHIBITING PURPOSES.

STAND OF ONE OF THE NEWCOMERS TO THE LIST: THE GARFORD MOTOR CAR COMPANY.

due to a desire to see and be seen—to let his competitors know that he was still on top. But with an inconsistency that ill-accorded with his statement he was continuously chasing the itinerant sign-painter to placard his exhibit with the names of new buyers as fast as cars were sold.

Bearing this in mind, as well as the fact that the American Motor Car Manufacturers' Association, the members of which

STURDY STUDEBAKER CONVEYS ITS LITTLE BROTHER TO THE SHOW.

form the virtual foundation of the show, have not had the advantages of co-operation for more than a few years, and the result as exemplified by the long lines of cars was something of which they may justly be proud. During the past week there was gathered in the Palace a very substantial percentage of the backbone of the American automobile industry as a whole, and

LANSDEN, WHICH EMPLOYS MUCH EXPLOITED EDISON BATTERY.

anyone who is conversant with prevailing conditions to-day could hardly fail to recognize this. It has been evident all along that ultimately the medium and low-priced cars must naturally constitute the bulk of the annual output, whether here or abroad, and the American makers who are numbered among the members of the A. M. C. M. A., as well as not a few of those who have not become affiliated as yet with any of the organizations in the field, have not been slow to realize and take due advantage of that fact.

To be more explicit regarding the show itself, it is safe to say that it represented as successful an affair of the kind as either of the

associations in question have ever been responsible for, and that is saying a great deal, as both last year's Palace show and the opening event of the kind in the Sixty-ninth Regiment armory were affairs that forcibly demonstrated what the independent makers were capable of in no uncertain manner.

Whether a mistake was made in setting the date of the show too far ahead, despite the evident demand for early shows, is something that cannot be answered at the moment, besides being a matter on which there is considerable difference of opinion. Involving as it does the question, "Do people now come to shows to actually place orders for cars?" it is difficult to say that a show held at any time near the closing of one season or the opening of another is premature. Those who uphold the view that the date was too early point to the fact that the attendance was not as great this year as last on the opening or the first three or four nights, to substantiate their opinions, but the peculiar conditions prevailing were largely accounted for by the fact that out-of-town autoists timed their visits in a great many instances so as to be in New York during the closing days of the Palace show and the opening of the Garden, so that there was considerable of an influx of new visitors as the show drew to an end. Besides this, there is another thing to be considered. Automobiles are so numerous on the streets nowadays that it is hardly necessary for the merely curious to attend a show.

Briefly summed up, however, the New York shows may or may not be longer necessary for the placing of agencies; that's a question for the makers to decide, and they ought to be able to answer it without any vast amount of figuring, for facts should exist, and facts are stubborn things. New York shows, like the shows in all other cities, are certain to help the retailing of cars, and if the metropolitan exhibitions are held for this particular purpose there isn't any doubt whatever but that they are too far ahead in the calendar.

SIX-CYLINDER COLT RUNABOUT, ONE OF THE SHOW'S FEATURES. 3

UNIQUE DASH ARRANGEMENT OF THE NEW ELLSWORTH.

WHERE THE GREAT CHADWICK SIXES WERE ARRAYED.

## SOME OF THE THINGS SEEN AT THE PALACE

By CHARLES B. HAYWARD.

TO the man with no eye for detail, be he technically inclined or otherwise, most four-cylinder and six-cylinder cars look alike, and as models of those types constitute the bulk of the cars shown, there is more or less sameness about the entire aggregation that leads the man in the street to the conclusion that all automobiles are alike. To a certain extent this must naturally be the case, but it does not require an unusually observant eye to note scores of points of difference that merit remark. For instance, such a very apparent exception to current practise in motor design as the placing of the flywheel at the forward end of the engine which characterizes the Maxwell product, is something that can hardly fail to draw the attention of the visitor with the least perception of detail, but as even such a very noticeable feature as this frequently escapes a great many of the would-be motor wise, it is hardly strange that finer points of design and construction should be overlooked entirely. This Maxwell characteristic has been perpetuated in the new 26-horsepower four-cylinder model which, owing to its low price, has come in for a great deal of favorable comment. Then there is the double-elliptic form of suspension which is also a feature of these cars as well as numerous others of the lighter types, such as the Ford and Reo, also of the medium weight class, as the Premier.

### Varying Standards of Suspension.

Speaking of springs, it does not take a great deal of observation to learn that makers generally have become divided into two or three well-defined schools where the matter of suspension is concerned. One of the most noticeable things in this connection is the vogue of the platform type or three-point suspension for medium and heavy cars, instances of this being found in the Garford, the Cleveland, American Mors, Pennsylvania, Dorris, Mora, National "little six" and the Great Chadwick, while the Austin is unique in having three-quarter rear or "demi-pincette" springs. The new Ellsworth, which combines so many novel and interesting features, is also noteworthy in this respect in that it is equipped with a special three-quarter type of forward spring, the upper half portion of the latter being riveted directly to the frame ends and taking the place of the usual dumb irons. Another special type is to be found in the American under-slung suspension which was first brought out last year, but which

always attracts a great deal of favorable attention owing to the unusually attractive lines it gives the car. Quite the most novel thing to be noted in this field is the combined helical spring and shock-absorber suspension of the Brush cars, while another car using this type of springs is the Lansden electric

EXHIBITION CHASSIS OF THE UNDERHUNG AMERICAN.

touring car in which they are employed to advantage together with solid tires of the twin type, providing unusually easy riding.

### Some Transmission Tendencies.

It was thought a few years ago that the planetary type of change-speed gear would soon cease to be a factor, but it requires very little observation to show that this is far from being the

HERE THE BIG AND LITTLE FORDS MET AN UNENDING STREAM OF ADMIRING FRIENDS.

FIG. 1. NIGHT VIEW OF THE MAIN AUDITORIUM WHICH SHELTERED PROMINENT CAR AND ACCESSORY EXHIBITORS.

case. In fact, the planetary gear is a feature of cars of both extremes, for it is found on the Reo single-cylinder runabout and on the Ford six-cylinder cars, as well as the new Gearless six-cylinder, although it is of a special type that is attracting a great deal of attention. The Gearless transmission is practically a friction drive type of planetary change-speed gear consisting of but three simple and substantially made parts, a cup, cone and cage of fiber-faced tapered rolls. The planetary gear is also a noticeable feature of the new Overland car, particularly owing to the radical departure made in its installation. This newcomer is a shaft-driven car, but instead of placing the gear-set directly back of the four-cylinder Rutenber motor which forms its power-plant, it is located at the rear end of the propeller shaft, just forward of the differential housing and in a separate inclosing case of its own, the high-speed clutch being made readily accessible for adjustment by means of a handhole. In all there are about twenty cars shown with planetary gears, representing eight or nine different makes, of which the Maxwell runabout, Moline and Atlas two-cylinder cars, Holsman and Kiblinger runabouts are some further instances. Exceptions to the practice of using this type on light cars and buggyabouts are to be found in the case of the Reliable Dayton with its sliding gear and the Schacht and Hatfield with a friction type. In the larger cars the friction drive finds its best examples in the Lambert, Cartercar and the Gearless. With these exceptions, the use of the selective type of sliding gear is almost universal on all except the lighter of the four-cylinder cars on which the only difference is the method of operation, such cars as the lower-priced models of the Mitchell, Moline, Dragon, Grout, Eagle and Maxwell, working on the progressive system. Cone and disk clutches and final shaft-drive are the predominant notes where the remaining essentials of the transmission are concerned, when taken in the aggregate.

#### Magneto Ignition Becoming Universal.

It takes but a glance to show the prevailing use of the magneto, and when it is considered that this is on cars where it was virtually unknown up to two years ago, suffices to indicate the extent to which mechanical generation is being adopted. The Dorris, Glide, Ellsworth, Frontenac, National, Welch, Allen-Kingston and Chadwick are a few on which the Bosch high-tension type is shown, such makes as the Rainier, Gaeth, Cleveland, Garford and Premier—the last-named an entirely new convert—using the same make in the low-tension type, while the Eise-mann is to be found on the Moon, De Luxe and a number of others, the Gianoli on the Frayer-Miller and the American Napier, the Remy on the Marmon, and the Holley on the Ford, all

these being of the high-tension order. In practically every case the standard form of high-tension ignition using accumulators or dry batteries as a current source, a primary timer and a four-unit coil is employed as a standby, and in the last-named rôles, the Splitdorf, Connecticut, Pittsfield, Kingston, Heinze, Autocoil and other makes figure prominently. The Ellsworth is a noticeable exception where its ignition arrangements are concerned, the Bosch high-tension magneto being placed in the hollow dash of the car which also shelters a twin-unit coil for the reserve side of the system. Despite the cost of a high-grade magneto of either type, they are now included as a part of the regular equipment of cars on which it was thought impossible to supply anything more ambitious than dry cells but a few years ago.

#### Some General Observations on New Things.

Considering as new cars all those which have never participated in a show, it is surprising the number to be seen in the Palace that can be included in this category, both those that are new in name and make as well as those that are entirely new designs by old-line makers. Under the latter heading must be included such productions as the new six-cylinder Premier with low-tension ignition, though of course most of the sixes are new in one sense, but in this case the design is entirely novel, which likewise applies to the showing of the Stoddard-Dayton with its specially designed motor, the water-cooled Marmon, the Great Chadwick Six, the Atlas three and four-cylinder, two-cycle cars, the Lansden electric touring car, the Jackson four-cylinder and one or two others. Then there are the new cars that have been out for several months, such as the Brush line, the Gearless, the Overland, the Allen-Kingston, and the like, as well as those that are brand new in both design and title, such as the Ellsworth. One of the noticeable things to the man who takes the trouble to look down at tires and rims is the general adoption of the detachable type of the latter, of which some prominent instances are the Goodrich on the Frayer-Miller and the Klink, the Goodyear on the Reo and Great Smith, the Midgley on the Mitchell, the Fisk on the Lambert and others, the adoption of Michelin tires by some American makers as regular equipment also being worthy of note. Of course, there are a number of instances in which some of these newcomers combine so many novel and interesting features that they can only be done justice to by a complete description, which is necessarily out of the question in any such casual review as this is intended to be. One or two instances of this that come to mind are the new Ellsworth, the Premier six-cylinder model and some medium-priced cars such as the Overland. Then there are the unusually low prices—but that is a story in itself.

# MEDIUM-PRICED CARS ARE INCREASING

By W. F. BRADLEY.

It is but natural that, in the automobile field, America should have found her widest field of activity in the production of vehicles intended for the man of average means. European constructors laid themselves out from the commencement to capture the wealthy who would take up their successive annual models without looking too closely at the price demanded for their acquisition. On this side of the Atlantic there was an early tendency to cater to the medium class trade and produce low-priced cars in big series which would find a ready market because of their democracy. The tendency has become such a national trait that when a European constructor decides to market a popular vehicle it is introduced as "American method." At the democratic show in the Grand Central Palace the popular automobile was not only much in evidence, but attracted attention because of its uniform excellence and the good value offered for a medium sum.

Prices, it is true, range all the way from \$250 to \$7,000, but it is in the class between \$1,500 and \$2,750 that the many attractive vehicles are to be found.

In view of what has been done by a few firms making a specialty of this class of business and the known activity of others to enter the low-price market, it would not be safe to predict that touring cars will never be built successfully and in any great numbers for less than \$1,500. Nevertheless, below this sum profitable construction becomes difficult and can only be successfully undertaken when it is possible to construct in exceptionally large series and market with the minimum expense. Automobile buggies must not be included in these generalities, for it is certain that within two or three years these vehicles will be in use in thousands in every rural district. In view of the special work they are built to perform, it would be more correct to classify them as commercial than pleasure vehicles.

At less than \$1,000 a dozen firms offer about twenty models, more than half of which are of the buggy type and only four are really four-seated touring cars. From \$1,000 to \$1,500 there are again a dozen firms with a score of models, four and five-seated touring cars predominating over two-seated runabouts. With a few exceptions, notable among them being Ford, Mitchell, Overland, and Jackson, the power plant consists of a single cylinder or a double opposed engine. Ignition invariably is jump spark with current obtained from storage batteries, magnetos unfortunately not yet being procurable in this country and the imported article being too costly to fit to a low-priced vehicle.

It is from \$1,500 to \$2,500 that the best value in the show is to be found, the cars between these two figures including some thirty makes, which, for general excellence and proportionate value for money, surpass both the lower and the highest priced classes. Striking an average, for \$2,200 there is a choice of nearly a score of four-cylinder touring cars which should appeal strongly to the man desiring a reliable, economical automobile sufficiently simple for him to attend to all its ordinary wants himself, powerful and roomy enough to carry four or five people at a moderate rate over average roads, and sufficiently light in construction to be economical in the use of tires.

There is a general uniformity in the mechanical features of the cars comprised in this class, four-cylinder engine forward, sliding gear transmission, generally of the selective type, and shaft drive. Two-cycle engines, planetary and friction transmission, have their share of supporters, but are really only a small part of the whole. As in the lower priced vehicles, electrical source is almost in-

variably obtained from storage batteries. The value of a magneto as a standard equipment is no longer doubted by any maker, but circumstances make it difficult to adopt this article for any car selling at less than \$2,500. Even at this figure more than 50 per cent. of the makers adhere to storage batteries, and only one \$1,500 car is listed with a magneto. As soon as the \$2,500 class is reached the prospective purchaser has the choice of ten different cars fitted with a reliable make of high-tension magneto.

Of equal interest to the amateur automobilist not overburdened with cash is ease of maintenance and accessibility of every mechanical part. The wages of a hired chauffeur being altogether out of proportion to the cost of a \$2,000 car, it is imperative that the popular machine should be of such simplicity that its owner can keep it in order with the minimum of labor. Where a skilled mechanic is engaged to tend an automobile, the matter of freedom from complications is of lesser importance, but for any popular machine simplicity must be developed to the utmost. Generally this has been realized by the manufacturers in their 1908 models, all the more glaring defects of a couple of years ago being remedied in the latest productions. Lubrication has been simplified and better provision made for attending to such parts as rear axle, differential, steering gear, and transmission. Although it is not anticipated that dismantling the engine will be a weekly occupation, design has been so simplified that in the majority of cases almost any part of the machinery can be examined with little trouble. There is still room for further development along this line, but when one remembers the models of a few years ago—some of them considered the best of their time—in which it required an hour's labor to open the gear box and the task of examining the main bearings were not to be undertaken unless one had an entire day to spare, the improvements of the 1908 popular models, as shown at the Grand Central Palace, are most satisfactory to the man who drives and cares for his own car.

## CANNOT BUILD A CAR UNDER \$1,500,

PARIS, Oct. 23.—Gustave Clément, one of the largest automobile constructors in France, and who has been prominent in the industry since the bicycle days, declares that there is not much to fear from the contemplated American invasion. The announcement was made on receipt of the news that a four-cylinder American car was to be placed on the French market at \$600.

"Not only is French workmanship superior to American, but we possess the same tools, and it is utterly impossible to construct a good touring car for less than \$1,500. Light machines built in America are good, perhaps, for the city, but never for the roads."

WHERE THE POPULAR-PRICED BRUSH WAS EXHIBITED.

ANNUAL SHOW. LUNCHEON OF THE AMERICAN MOTOR CAR MANUFACTURERS' ASSOCIATION, HELD AT THE HOTEL MANHATTAN, NEW YORK CITY, TUESDAY, OCTOBER 29

# A. M. C. M. A. AUTOMOBILE SHOW LUNCHEON

It was a notable array of automobile interests represented in the annual show luncheon of the American Motor Car Manufacturers' Association, held at the Hotel Manhattan, Tuesday, beginning at 1 P.M. Job E. Hedges filled the toastmaster's rôle in his usual brilliant manner, his vein of seriousness being meagerly interjected into his infectious humor. Benjamin Briscoe, chairman of the A. M. C. M. A. Committee of Management, was the chief spokesman of the "Independents," and H. O. Smith, chairman of its Show Committee, also contributed words of wisdom. In the absence of President Colgate Hoyt, who was said to be busy down in Wall street, ex-President Winthrop E. Scarritt spoke for the Automobile Club of America. General George Moore Smith, chairman of its Show Committee, said that illness had kept him from doing much work for the exhibition, and he generalized more or less about the kind of an automobile that he considered ought to be manufactured. T. F. Moore had something to say about the stock chassis race, which he is endeavoring to promote for a spring event.

Alfred Reeves, general manager of the A. M. C. M. A., came in for a generous amount of credit in connection with the affairs of the association and the success of the show. Secretary S. M. Butler, of the A. C. A., was among those at the speakers' table, and one who realized the enormous amount of labor which devolved upon his shoulders in connection with the show commented upon the lack of public mention of such an excellent soldier, whose work equaled that of a chairman. Telharmonic music and a flashlight photograph were included in the function, which also had souvenirs in the form of scarf pins.

In the course of his remarks, Chairman Briscoe said:

"I wish to welcome you to this our second annual luncheon, and thank you for the encouragement that your presence here lends. This association feels that it has many blessings. The friendliness of the Automobile Club of America; the kindly consideration of the daily press and the trade press; and the well wishes of the trade at large. We believe also that we have the personal friendship and respect and well wishes, perhaps not in a business sense, of those who are not of our particular household of faith. I presume that in an address of this kind one should stick closely to glittering generalities, but permit me to indulge in a few little association statements that tell why we are leaders in the industry. This association is the largest organization in the manufacturing industry. It has done much for its members and for the trade at large, for it has, with a true American spirit, fought for an independence in this particular industry which has undoubtedly done much to bring about a better development for the American automobile. This association bears no ill will toward any; it harbors no malice; and goes along attending to its own business and, if press reports are to be relied upon, its business constitutes a very large proportion of this particular industry. Of course, if it has any time left over, it attends to those who attend to its business. It believes that all the brains and all the ability are not even yet developed to the full benefit of the American motor car, and it also believes that not the only ones are those of the bluest blood or the purest aristocracy who maintain in their headquarters pieces of antique furniture, as it has been demonstrated that much of the antique is but a replica with many evidences of modern handiwork. It believes that success in the automobile business can only be attained by modern methods, and that every movement forward must feel fresher initiative and invention and it opines that the sequestered idol must needs be rejuvenated and renovated constantly to be maintained as a contributory shrine. Now I trust that I may have said nothing the least discourteous or that to it may be taken the slightest umbrage, for there is no class that we admire more, whose friendship we esteem more highly, than that of our friends, the stalwarts, who stick to their principles, even though they are parties to a contract. Our association is open to them and to any legitimate manufacturer in the industry.

"I desire to thank our eminent friend, Mr. Hedges, who so kindly consented to act as chairman of the steering committee on this occasion, and I desire to say to him that this association owes much to his advice and to his counsel. We thank him for it, and thus I pay him his retainer for another year."

The guest list included the following:

- |                       |                       |                       |

## MR. STEENSTRUP ON EUROPEAN SITUATION.

Peter S. Steenstrup, sales manager of the Hyatt Roller Bearing Company, of Harrison, N. J., returned recently from an extended European trip in the interests of his firm. According to Mr. Steenstrup, the foreign outlook could be more promising than it is, though the results of his trip were uniformly successful. According to Mr. Steenstrup, there has been some overproduction, and the foreigners are considerably disappointed at their inability to hold as much of the American market as formerly. Nevertheless, they profess no fear whatever from the possible invasion of Europe by American makers.

## A CHAPTER OF GOSSIP OF THE PALACE SHOW

Ever since the Automobile Club of America was organized there has been a persistent worker in the background, one who never seeks the limelight, one ever willing to share with others the credit for things accomplished, and to whose untiring efforts is unquestionably due a vast amount of the success of this great big club with its palatial home in West Fifty-fourth street. Secretary S. M. Butler is the hidden mainspring in the works, a master of detail, patient and diplomatic, seldom ruffled, and treating all comers with uniform courtesy. Were it not for "Sam" Butler the A. C. A. would not have been the powerful factor which it is in automobiling, nor would the organization have continued in the show business after the severance of its connection with the Garden affairs. Butler it was who argued, and successfully too, that the club could not afford to relinquish its work in the direction of show promoting, and, forcing the issue, there came the arrangement with the "Independents" and the notable exhibition of 1906 in the Sixty-ninth Regiment Armory. It will be a day of sorrow for the A. C. A. if it should ever lose the services of its secretary. Presidents are made; good secretaries are born.

\* \* \* \*

There is another organization the burden of whose success also traces back to a persistent worker, whose skilful direction of affairs has brought order out of chaos and caused the adoption of a consistent policy which has been of great benefit to the membership. "Al" Reeves has accomplished much for the American Motor Car Manufacturers' Association since he took the office of general manager less than two years ago. The results of his labors were apparent in the January, 1907, show, and they have been even more apparent in the October exhibition which closes to-night. Reeves never seems to weary, and he is always on the job from early in the day until well into the night, if it be necessary. Understanding the value of publicity and knowing how to obtain it, he has made the A. M. C. M. A., from something that was scarcely more than a name, into an association which has caused the "other camp" to be on its mettle and carefully watchful of the moves of the "Independents." Reeves ought to be able to size up the European situation accurately and bring back information upon which the members of his association should realize profitably.

\* \* \* \*

**Benjamin Briscoe (Maxwell-Briscoe).**—"It is the finest show we have ever held. We never did better business and we never had more reason to be satisfied. The class of trade represented at this show has not been affected by the financial disturbance."

\* \* \* \*

**H. O. Smith (Premier).**—"We need one big national show, in which all questions of creed and doctrine shall be dropped; a show of such magnitude that the public will be able to realize what a big industry this is. Probably the best time would be August, the date being arranged to suit the rural populations, which are becoming more and more interested in automobiles. For the good of the industry it would be desirable as far as possible to obliterate the definite marking of the various seasons. The automobile is a practical conveyance, and as such is useful all the year around. The financial disturbance is only temporary and local; we should act cautiously, but without fear."

\* \* \* \*

**J. B. Bartholomew (Glide).**—"There is no doubt that the show has been an excellent one. I should prefer an outdoor show in August, with important races as an attraction. There is nothing to fear from the financial disturbance. Wall street is not the whole country."

\* \* \* \*

**R. E. Olds (Reo).**—"It was unfortunate that a financial disturbance should have arrived at the opening of the show season, for the newspapers have had no space to spare for our do-

ings. October is too much in the fall to be the most satisfactory show date. January would suit best of all. Shows are no longer useful as a selling force. I should like to see a huge outdoor exhibition in summer. At present the public does not realize what a stupendous industry this is."

\* \* \* \*

**S. H. Mora (Mora).**—

"Is the early show satisfactory?"

"Well—have you had your dinner?"

"Yes."

"Will you have another?"

"No, thanks."

"Just the same with the shows. We have been handling automobiles all the summer and we have no appetite for another feed. I voted for an early show, but now think December the finest proposition. The financial situation won't harm. Nineteen hundred and seven was a slow year; numbers of people kept their old cars; next season there will be a proportionate boom."

\* \* \* \*

**A. C. Newby (National).**—"Early shows are good, but this one is not early enough. The best proposition is an outdoor show in August. Before the Long Island parkway was proposed I was interested in a five-mile race course on Long Island, which would have been an ideal spot for a national summer outdoor show; an attractive race program would have guaranteed huge crowds. We have still need of such a track, and if the East does not build it the West will. There is an excellent site for such a course in Indiana, in which a number of us are interested. Next year the show will probably be in September, and the following year will see it in August, and outdoors."

\* \* \* \*

**R. Harry Croninger (Pennsylvania).**—"Shows do not now sell automobiles. They are valuable as a means of publicity, but the actual selling is done by agents, who come directly to the factory and have no real need of a show. I am not an advocate of a yearly show, nor of a yearly model; thus date is immaterial to me. Sales have been few, for the public is waiting for the Garden show, and the financial disturbance has had a bad influence. But the trouble is only local and has not even been felt in a city so near as Philadelphia."

\* \* \* \*

**H. B. Larzelere (Chadwick).**—"An excellent show in every respect. Sales on the whole have been poor, though we have no complaint to make. A number of small firms from the West, exhibiting for the first time, have forgotten to reckon with the big manufacturers of cheap cars, and will have to go under. There will be a weeding out next season, and during the following year more money than ever will be made in the automobile business. Shows are now of minor importance as a retail selling factor."

\* \* \* \*

**Howard Marmon (Marmon).**—"We have had to hustle to get ready for the earlier show, for it was necessary to gain a couple of months. The new date is satisfactory from a manufacturing standpoint, for it gives more time to produce the year's models. Two shows in close succession are good. Hundreds who would have had to decide between one or the other can now visit both."

\* \* \* \*

**N. A. A. M. Had Small Amount in Knickerbocker.**—A rumor came to the surface during the week that the N. A. A. M. had a considerable amount deposited in the Knickerbocker Trust Company. The report was erroneous, and General Manager S. A. Miles said that the amount was comparatively small, for the National Association has its funds deposited elsewhere.

## BROOKLANDS RACING SATISFACTORY.

LONDON, Oct. 24.—Last Saturday's meet at Brooklands—the fifth and final for this season—proved to be the most interesting that has yet been held. There was an entire absence of the interminable waits between events so characteristic of previous meets, and a new rule requiring all cars to be filled with exhaust boxes greatly added to the comfort of the spectators.

Prompt to time the Medium Handicap Sweepstakes was run off, the limiting cylinder dimensions (D<sup>3</sup>N) being 104-122. Of the nine entrants, the most interesting—the Brasier which won the last Gordon-Bennett—was unable to start; nevertheless, plenty of excitement was provided by the race, which led to a win by the 48-horsepower Metallurgique, with an average speed of 62 miles an hour over the five-mile course. A Pipe was second and Huntley Walker's Darracq was third.

Without any delay the 26-horsepower cars were lined up for the next event. A close race between a Metallurgique and a Napier proved a narrow victory for the latter, third place falling to the Arroll Johnston. The winning Napier was originally a six-cylinder model, but to bring it within the prescribed limits the two front cylinders were removed, a new crankshaft and valve gear fitted, and a fast and efficient four-cylinder car was thus evolved.

The October Handicap was won by Fry's new 75-horsepower Mercedes (really one of the 135-horsepower racers). This car also won the race for 90-horsepower cars with an average speed of 92 miles an hour for the 21 miles. In this latter race a 120-horsepower Fiat should have taken second place, but at the entrance to the finishing straight the driver mistook the signal and kept to the outer course, allowing the Hotchkiss 130-horsepower car to come up meanwhile and gain second award.

The 60-horsepower race brought out another Napier as a winner, as before closely followed by a Metallurgique. A higher powered Napier than the winner only managed to take third place.

The best race of the day was seen in the following event, a

private match between a Napier and an Iris—a Dennis car, which also ran, being out of it from the first. Right at the start the two cars got together and at half way but three yards separated the Napier from the Iris, which followed it. Nearing the finish the Iris made a sudden spurt (presumably oxygen), but just failed to win by the length of the Napier's bonnet.

No further race meeting will be held on the track this year, for, although a big meet was planned for the time of the Olympic show next month, the trade rather objected to such a diversion from serious work and the scheme was in consequence abandoned.

## EDGE TO BEAT RAILWAY RECORDS.

LONDON, Oct. 24.—The ubiquitous S. F. Edge is not at all satisfied with his recent 24-hour record and proposes to startle the world with another big achievement. The fastest express train between London and Edinburgh travels over the North Western and Caledonian lines and is booked through in eight hours, an average speed of just 50 miles an hour. Edge has wagered a big sum with the Hon. Dudley Carlton that he will cover this 400 miles in five and one-half hours in a 60-horsepower Napier, equipped with flanged wheels to run on the railroad tracks. If the necessary permission can be obtained the run will shortly take place. The loser will pay the amount of the wager to the Railwaymen's Orphanage.

## U. S. A. INTERESTED IN PARIS CONFERENCE.

PARIS, Oct. 21.—Alcohol, touring and motor boats are the three subjects for special international conferences during the three weeks of the Paris Salon. Most important results are expected from the conference on denatured alcohol. Frank Rutter, of the United States Department of Agriculture, has written to Gustave Rives asking for information on the matters to be discussed at the denatured alcohol conference, and declaring his intention of being present.

BROOKLANDS COURSE AS SEEN FROM THE MEMBERS' ENCLOSURE, SHOWING VAST EXPANSE OF TRACK SURFACE.

## TO SECURE GOOD ROADS: MAKE FARMER AN AUTOIST

PHILADELPHIA, Oct. 28.—Many of the more prominent local automobilists journeyed out to Swarthmore last Saturday afternoon, where fully 250 enthusiasts had gathered at Strath Haven Inn, as guests of the Good Roads Association of Delaware county, to discuss the various phases of improved highways. First, however, they discussed a bountiful banquet, after which, without moving from their places at the table, the convention was called to order. Besides the local lights, there were several prominent good roads enthusiasts present from New Jersey, Delaware, New York, and other States. One of the headliners, State Highway Commissioner McDonald, of Connecticut, failed to reach Swarthmore in time, but sent a telegram.

The president of the Automobile Club of Delaware county, J. W. Weeks, was in the chair, and after announcing the objects of the gathering introduced "Good Roads" Sproul, the State Senator after whom the present good roads law of Pennsylvania is named. The Senator urged the people—the townships and the boroughs—to take hold of the problem at once and not wait for help from the State, although he admitted that Pennsylvania would eventually be forced to follow the example of New York in the building and maintenance of main highways.

R. J. Baldwin, road supervisor of Birmingham township, made quite a hit when he urged the automobilists to endeavor to interest the farmer in the motor vehicle. "Get in touch with the makers of \$350 and \$400 cars," he said, "and find some means of introducing these machines among our farmers, and it would not be long before the latter would be anxious to co-operate with us. And the result would be such that there would be no difficulty in carrying on the work after a start had been made. Improve our pike roads and the \$30-an-acre farms would soon command

\$100 an acre. As an instrument in promoting the good roads cause there is nothing in the same class with the automobile. I urge you to make automobilists of our farmers."

So impressed was President Weeks by Mr. Baldwin's suggestion that before introducing the next speaker he promised to introduce the matter at the next meeting of his club.

William I. Schaffer, official reporter of the Supreme Court of Pennsylvania, said that "as a Delaware countian, Senator Sproul had begun the agitation that had resulted in the passage of the present good roads law, it was eminently fitting that our county should lead the State in interest, enthusiasm and the fight for proper legislation on the subject. The State," continued Mr. Schaffer, "should build great highways from Philadelphia to Pittsburgh, from the latter city to Erie, thence to Wayne county and along the western border of the State."

Highway Commissioner Joseph W. Hunter expressed himself in favor of a \$25,000,000 or \$50,000,000 loan, as the project was much too vast for the township to handle properly. He called attention to the fact that since he took charge of the State's good roads work over 300 miles of improved highways had been built. "The mere building of good roads, however," said the commissioner, "is the easiest part of it. The real problem is the future maintenance of these improved highways."

Addresses were also made by Isaac B. Potter, of New York; District Attorney McDade, of Delaware county, and J. R. Robinson, chairman of the Law Committee of the Automobile Club of Delaware county. Before adjournment President Weeks announced that another meeting would be held in a few weeks to take initial steps for the improvement of the Wilmington and the Baltimore pikes.

## SENSIBLE MASSACHUSETTS PLAN OF OBTAINING NEW LAW

SPRINGFIELD, MASS., Oct. 28.—At the suggestion of former State Senator M. A. Morse, of Belchertown, now a lecturer of the State Grange, a committee of the State Grange, representing the farmers, and a committee representing the automobile clubs of the State will hold a joint conference for the purpose of agreeing upon a new automobile law to be introduced into the Legislature during the next session.

By means of the conference former Senator Morse hopes to overcome the prejudices that exist among the farmers against the automobile, owing to ignorance, and to show the automobilists wherein they have transgressed against the farmers' rights. Such a conference, he believes, will result in a State law which will be more satisfactory to both sides than any of the present legislation.

For the automobilist, it will be the purpose of the conference to inculcate into the new law an article permitting the autoist to go as fast as he pleases on an open straight road where there is

absolutely no danger to pedestrians, and to do away with the closed road situation existing in a large number of the towns in the Commonwealth, notably Nantucket.

For the farmers, it will be the desire of the grange committee to get fair, equitable restrictions on speed near crossroads and on curves, and general rules of the road that will reduce to a minimum the chances of the farmer's horse taking fright at the passing of an automobile.

Mr. Morse will place his scheme before the annual meeting of the State Grange in Pittsfield in December, and he has already received assurances from members of the granges all over the State that the plan will be considered favorably at that session. Interviews with leading autoists in the different parts of the State have convinced him that the automobilist will be quick to embrace the scheme, and the prospects are now that a first-class State law will be drafted at that time which will receive the support of the farmers and autoists throughout the entire State.

### NEW YORK OFFICE FOR REGISTRATION.

A convenience to metropolitan automobilists who desire to tour in New Jersey and Pennsylvania and find it necessary to secure their registration in something of a hurry, will be found at 197 Fulton street, New York City, where the president of the Brooke Automobile Supply Company acts as an agent for the New Jersey Commissioner of Motor Vehicles, and also as a representative of the Pennsylvania State Highway Department. This makes it possible to accomplish registrations and at the same time have your car equipped with hangers and lamp numbers five minutes after signing the necessary applications.

### RESTRICTIVE LEGISLATION IN ONTARIO.

The report emanates from Toronto that there is to be war on the automobile at the coming session of the Ontario Legislature. The initiative will be taken by the members representing a number of rural constituencies. It does not appear to be a party question, for those planning action are seated on both sides of the House, though the large majority are Conservatives. It is reported that an authenticated list of casualties during the past eight months is being prepared for presentation. This includes the ditching of over thirty farmers' vehicles on rural roads.

## REEVES TO LOOK INTO EUROPEAN MARKET

LONDON'S annual automobile show at Olympia and the Automobile Club of France's tenth annual salon in the Grand Palais are to be visited by Alfred Reeves, general manager of the American Motor Car Manufacturers' Association. The visit is the result of a decision arrived at at Monday's meeting of the Committee of Management of the association, its manager being charged to inquire into the European situation with a view to a possible invasion of the foreign field by the fifty-one manufacturers holding membership in the A. M. C. M. A. The London show being held from November 11 to 23 and the Paris exhibition from November 12 to December 1, Mr. Reeves will sail for Europe soon after the closing of the Palace show.

In addition to visiting the two national exhibitions, Mr. Reeves will make inquiries as to the best methods of selling cars, whether through agents or branch houses, the best plans of advertising for foreign countries, and other matters. In view of the entirely different methods of selling in most of the countries of Europe, and the small amount of attention which has

hitherto been paid to this matter by American firms, it is expected that the report of investigations which Mr. Reeves will present before his association will be of considerable interest. It is also proposed to consider the advisability of a joint American exhibition at the Paris and London shows next year to be participated in by all members of the A. M. C. M. A.

At the same meeting of the association it was decided to work further on the matter of admitting gasoline trucks to the docks and piers of New York, and to start a campaign in other seaboard cities. About half the docks in New York now permit their use.

The idea of a stock chassis race in the spring under proper management was strongly endorsed. It was recommended that it be held early in May.

B. F. Everitt of the Wayne Automobile Company was elected a member of the Committee of Management. In attendance at the meeting were Benjamin Briscoe (Maxwell), Chairman; R. E. Olds (Reo), W. H. Van Dervoort (Moline), Charles Lewis (Jackson), C. C. Hanch (Marmon), J. H. Bartholomew (Glide), A. C. Newby (National), and Charles E. Duryea.

## BRITISH MAKERS AFTER AUTOIST OF MODERATE MEANS

LONDON, Oct. 24.—With the approach of the Olympia Show, the usual rumors of immense price reductions are in evidence, but direct inquiry reveals the fact that, for the most part, these reductions are merely nominal, and in cases where a distinct drop in prices is to be made it is occasioned by the production of a lower powered model. Napier started the list of 1908 announcements with the news of their 30-horsepower six-cylinder car, to sell at \$2,875, chassis with tires. This is undoubtedly a big drop for Napier, whose previous six-cylinder models have been listed in the region of \$5,000, but by complete standardization this lower powered but high grade model becomes a commercial proposition at the low figure mentioned. Daimlers, too, are credited with the production of a new model of about 20 horsepower, to have live axle drive, and selling at \$2,250 or so. Lower down the scale Humbers, at their immense new

Coventry factory, plan to turn out 4,000 cars of 10-12 horsepower at \$1,375, and it is around this power and price that the keenest competition will center. Some of the highest grade French makers are reported to be busy with cars of this type, and the exclusive manufacture of high-powered cars will be abandoned. The Mercedes people themselves were supposed to be bringing out a medium priced car, but this plan will probably not mature until 1909 season, though the Austrian branch of the Mercedes company is straightway putting on the British market a 25-horsepower car at a moderate figure.

Full details of the new season's productions of most of the makers are not yet available, but there is no doubt that attention is now everywhere turned to the "autoist of moderate means," and it is for his favor that the manufacturers and their agents will struggle next year.

### "ISOLATED" EXHIBITS DURING SHOW SEASON.

While the fortnight of shows is in progress the Waldorf-Astoria and the Breslin hotels each invite to a one-firm exhibition. At the former the American Locomotive Automobile Company exhibits its 1908 models built under the French Berliet license. Prominent in the series is the new six-cylinder touring car and a new shaft-driven four-cylinder town car fitted with closed body.

In the public room on the ground floor of the Breslin the Atlas runabout is being exhibited during the Palace show week and will be replaced during the Garden show by a new Oldsmobile.

The Rambler cars, unable to secure all the space their manufacturers wished for them in the Palace show, are being exposed at the showrooms of Homan & Schulz Company, West Sixty-second street. Three cars and one polished chassis are on view.

### GEARLESS NOT MAKING TWO-CYCLE MOTORS.

In the last issue of THE AUTOMOBILE, under date of October 17, it was erroneously stated, in giving a description of the exhibit of the Gearless Transmission Company, Rochester, N. Y., that this concern was devoting its attention to the manufacture of four and six-cylinder cars equipped with two-cycle engines. The error was due entirely to a misunderstanding, as this firm only builds four-cycle engines in the four and six-cylinder sizes.

### ANOTHER AUTOMOBILE FROM NEW HAVEN.

NEW HAVEN, CONN., Oct. 28.—The Connecticut Automobile Works, a stock company of out-of-town capitalists, has leased one of the largest factories in this city, formerly occupied by the National Folding Box & Paper Company. This factory is to be equipped with new modern machinery for the manufacture of automobiles and commercial vehicles and will start operation early next month. The company will manufacture three distinct styles of automobiles, touring cars, runabouts, and trucks. The entire building, which is one of the largest in this city, will be occupied by the new concern, and on the first floor will be a large showroom and a demonstration room.

### BERLIET "SIX" SELLING PRICE IS \$7,500.

Owing to an error in the caption under the illustration of the six-cylinder American Locomotive car, manufactured under Berliet license by the American Locomotive Automobile Company, and appearing in our last week's issue, the price of the latest production of this firm was made to appear ridiculously low. Instead of \$4,500, it should have read \$7,500. The car was not exhibited at the Grand Central Palace show, but during the fortnight of shows is forming the center of attraction at the company's special salesrooms in the Waldorf-Astoria.

**American Makers Fill the Garden for the First Time.** Though the show which has held the boards at the Grand Central Palace during the past week will go down into history as the first to have the honor of being an “all-American” show, the fact that Saturday the Madison Square Garden will be thrown open to the public to view an aggregation of cars and accessories also of purely American manufacture seems of more considerable import, due to the fact that much of the history of American automobile shows clusters about the Garden. Our British cousins have taken an immense amount of patriotic pride in referring to cars assembled in toto from French and German parts as “all-British,” but this is not the case with this all-American show, as it is everything that the name implies, and as such cannot fail to mark an epoch in the history of the industry. The early struggles of the American maker, both in building and showing a practical automobile, are all inseparably associated with the Garden, so that the fact that American makers are now filling it from top to bottom with products in the shape of cars and accessories is of far greater significance than may appear at first sight. In all previous years foreign cars have formed a very appreciable part of the showing, gradually dwindling until now, when they have been eliminated entirely. As the number of exhibitors is greater than at any previous affair of the kind, it bears striking testimony to the successful growth of the American industry during the few short years that mark the period of its existence.

**Adjusting the Rights of All Users of the Road.** In an article carefully prepared, giving the automobile its full meed of consideration and setting forth the rights of other vehicles of the road, Henry B. Anderson, in the November *Century*, presents the problem concisely in this sentence:

“The manner of use is the important consideration, and it is plain that there is a nice balance to adjust between the rights of those endeavoring to benefit by this means of transportation and those who are unwilling or unable to do so.”

Mr. Anderson says the right to use the road “is a common one,” and further on remarks that “what is done in the way of regulation should encourage the most efficient methods of transportation.” A point is made of the difference between technical speed violation and driving to the public danger, and reference is made to the practice of “trapping” on measured stretches where traffic is not congested and giving no heed to reckless driving in crowded thoroughfares as long as it is within the legal speed.

Mr. Anderson contends for the licensing of drivers, calling attention to the fact that “An inexperienced man may buy a car and at once go forth to experiment upon the public.”

The dust nuisance, Mr. Anderson thinks, and other minor evils of automobiling is awakening the whole country to an interest in the improvement of the roads. The benefits of better highways “will not be wholly to those who motor for pleasure or transport, for ultimately will come a local cheap and rapid distribution which may render communities largely independent of railways.”

The comments of this writer are eminently fair and well worth the perusal of the owner, the man who hopes some day to own and those who have the desire and not the means to consummate their wish. But some day everyone, in some form or another, will benefit by motor-driven transportation.

**To What Extent Does the Auto Damage the Roads?**

“Give a dog a bad name and hang him” has seldom been better exemplified than in the case of the accusation against the automobile in the matter of road damage. It must be conceded once and for all that the automobile does wear out the roads—the very best of roads—but whether it does so to anything like the extent that those road supervisors who can only view the matter through prejudiced eyes would have the rest of the world believe, is a horse of quite another color. But it has become quite the fashion to blame the automobile for anything and everything, from the spread of the gypsy moth to a falling off in church attendance, and so it is that on it falls the entire onus of utterly ruining roadways, which, it must be inferred, would otherwise last forever. Both the automobile and the road damage it does are new things, and, as a consequence, there has been too much of heated accusation on one hand, with retort in kind on the other, and far too little calm consideration to have made any progress possible.

The roadbuilder and local taxpayer point with wrath to newly corrugated surfaces and disintegrated top dressings that bear the tell-tale imprint of pneumatic tires, and, in kindred spirit, the autoist resorts to the *tu quoque* argument, calling attention to the road-destroying ruts made by narrow tires and holes dug by sharp iron hoofs. It is high time to recognize the fact that roads cannot be used without wearing out, and everything passing over them contributes to the wear to some extent. But we have been accustomed to the unsightly and destructive ruts and holes of horse traffic ever since there has been such a thing as a road; the damage created by the automobile is something novel. Hence, the primal cause of the road’s rapid disintegration is overlooked. Unfortunately, however, the automobile takes up the work where the horse leaves off, and, the evidences of its crime being so different, it is accused of being responsible for the entire damage. It does not take an expert road-builder, to show the fallacy of such a theory, and any unbiased observer must admit that the automobile’s share of damage does not exceed that of the horse. But a moment’s consideration is necessary to show that the automobile has advanced the art of road-building and the spread of good roads more than any other single agency.

## TO RACE OR NOT TO RACE; ON CIRCULAR HORSE TRACKS?

It would appear from the suggestions of the special commission asked to consider the question of continuance of sanction granting by the A. A. A. Racing Board for competition on tracks originally constructed for horse racing, that such future competition will be so hampered with restrictions as to make it more or less prohibitive in many cities where such tracks exist.

The special commission, consisting of S. A. Miles, of the N. A. A. M.; Benjamin Briscoe, of the A. M. C. M. A.; Percy Owen, of the Importers' Automobile Salon, and President William H. Hotchkiss and Racing Chairman Jefferson deMont Thompson, of the A. A. A., held a prolonged session at No. 437 Fifth avenue, Tuesday morning. Charles Clifton, of the A. L. A. M., was unable to be present.

After a thorough and exhausted discussion, it was the opinion of the committee that no definite action on the subject be taken until the various suggestions below embodied should be referred to the several organizations represented on the committee. The suggestions will at once be submitted for action to the various organizations, and another meeting will be held at an early date. In specifying the conditions under which sanctions should be granted, the commission put forth these propositions:

- 1.—That the application be made through or by a club or organization which is a member of the A. A. A.
- 2.—That such application be so made at least six weeks before the date set for the contest; provided that in case a sanction has been granted for a contest on such track prior to the date of such application and after the investigation and under the conditions here outlined, such second or other application can be made within a shorter time before the date set for the contest.
- 3.—That such application be accompanied by a photograph or photographs, showing the turns of such track and the location of the grandstand and public enclosures thereon, and also by an accurate drawing and specifications of the track, fences, and structures adjacent.
- 4.—That such application be also accompanied by a certificate of such club or organization, that it has examined such track and the fences and buildings adjacent, and that in its opinion, the contest or contests for which sanction is asked can be held thereon with reasonable safety to spectators and participants; which certificate must contain an agreement upon the part of such club or association that the public will be limited to certain portions of such buildings or grounds (specifying them), and excluded from all other portions thereof.
- 5.—That such application include the nomination of a person or persons whom or from whom the Racing Board may appoint a referee, who, at such contests, shall be the official representative of such Board, and charged with the duty of compelling the observance of all stipulations specified in such application and sanction, as well as the rules of the Racing Board in particular as to the competency of drivers and the mechanical condition of cars.
- 6.—That sanctions on such applications be granted by the Racing

Board only after an investigation of the track, fences, buildings, and adjacent grounds, to be made by such Board or a member of it or a competent engineer appointed by it for that purpose.

- 7.—That all sanctions granted by the Racing Board specify
  - (a) The number of cars which may take part in any heat, and
  - (b) The upward limit of the horsepower of such cars, the same to be fixed by a formula to be subsequently announced, as to which limit of horsepower and as to which formula the Committee requests the advice of the various organizations represented.
- 8.—That applications for sanctions be accompanied by a sufficient fee, to be fixed by the Racing Board, to cover all its expenses in connection with the examination of the track and its surroundings, as well as the reasonable compensation and expenses of any referee it may appoint as its representative.

As a part of the proceedings, a report was presented summarizing the vote of the A. A. A. clubs which have, thus far, taken action for or against the granting of future sanctions on horse tracks as now constructed:

### In Favor of Sanctions Unqualifiedly.

Milwaukee A. C. Motor Car Racing Association of Baltimore (Md.).

### In Favor of Sanctions but with Restrictions.

Chicago A. C. Quaker City Motor Club of Philadelphia.  
Bay State Automobile Ass'n.

### Against Such Sanctions.

Cincinnati A. C. Cass County (Ind.) A. C.  
Massachusetts A. C. Central Pennsylvania A. C.  
Pittsburg A. C. Janesville (Wis.) A. C.  
Rhode Island A. C. Auburn (N. Y.) A. C.  
Rochester A. C. Grand Rapids (Mich.) A. C.  
Buffalo A. C. Schenectady (N. Y.) A. C.  
Cleveland A. C. Worcester (Mass.) A. C.  
Wilkes-Barre A. C. Long Island A. C.  
Albany A. C. Weld County (Col.) A. C.  
Wilkesburg (Pa.) A. C. St. Louis A. C.  
Springfield (O.) A. C. Owatonna (Minn.) A. C.  
Detroit A. C. N. J. Auto. and Motor Club.  
Brockton (Mass.) A. C. Lima (O.) A. C.  
Peoria (Ill.) A. C.

### Against Sanctions in Opinion of Secretaries (No Action).

Oswego (N. Y.) A. C. Bloomington (Ill.) A. C.  
Springfield (Ill.) A. C.

### No Action Either Way.

Springfield (Mass.) A. C. New Britain (Conn.) A. C.  
Malden (Mass.) A. C. Adirondack A. C., Sandy Hill, N. Y.  
Washington (D. C.) A. C. Binghamton (N. Y.) A. C.  
North Jersey A. C.

A majority of the clubs so voting, however, expressed the belief that automobile racing should be continued on either specially constructed tracks, or, under restrictions and supervisions which would make such racing safe to spectators and participants. The call for this vote was not sent out until October 7, hence many clubs have not yet taken official action.

## TRADE DIRECTORY IMPROVED AND ENLARGED.

Keeping pace with the extraordinary growth of the automobile industry, "THE AUTOMOBILE Trade Directory," published quarterly by the Class Journal Company, Flatiron Building, New York City, has increased in size and importance with each succeeding issue. The October number, which has just made its appearance, has been completely revised and rearranged and contains a number of new features, among them being the listing of trade names as well as manufacturers' names in alphabetical order. The book thus comprises practically a double index of every automobile manufacturer, maker of accessories, and all firms connected with the operation and maintenance of automobiles. As an example of the completeness of this issue it might be mentioned that even such subjects as putty, thread, lamp wicks, etc., are listed. Steel alone has been covered by a dozen classifications, which include all the alloy steels, such as chrome nickel, nickel, manganese, and vanadium steels. The listing of the manufacture of special machinery and machine tools used by manufacturers and repair men alone requires eight pages and over fifty headings.

The growth in size of the publication will best be seen by a comparison with earlier numbers. In April, 1904, "THE AUTOMOBILE Trade Directory" contained 66 pages, 19 advertising pages, and 240 classified headings. The latest number contains a total of 296 pages, 144 advertising pages, and nearly 500 classified headings, and lists about 4,000 companies.

## A. A. A. ISSUES A YEAR BOOK.

The A. A. A. has issued its first "Year Book," containing all sorts of information about the national organization of automobilists. There is a brief history of the association since its formation in 1902; chapters on legislative, touring, good roads, and racing boards; lists of officers and club members of the various State associations; copies of the Federal registration bill, and also of the uniform State motor vehicle measure; information as to the plan of forming State associations and clubs; a table of existing State laws; list of road and track racing records, as well as half tones of the officers, and other material. President William H. Hotchkiss is really responsible for the issuing of the "Year Book," the work having been accomplished under his immediate direction. All members of the association will receive a copy of the book, and the first edition will consist of 20,000 copies.

## A. A. A. MEETINGS DURING GARDEN SHOW.

- Meeting of the A. A. A. Touring Board, Wednesday, Nov. 6, 2 P.M., No. 437 Fifth avenue.
- Annual meeting of the A. A. A. Board of Directors, Thursday, November 7, 10 A.M., No. 437 Fifth avenue.
- Meeting A. A. A. Racing Board, Thursday, November 7, 3 P.M., No. 437 Fifth avenue.
- A. A. A. Good Roads Convention, Friday, November 8, 10:30 A.M., No. 437 Fifth avenue.
- Meeting New York State Automobile Association, Friday, November 8, 2:30 P.M., No. 437 Fifth avenue.

## EVENTS ARE NOW MULTIPLYING IN CLUBDOM

### WORCESTER CLUB BEGINS WINTER SEASON.

WORCESTER, MASS., Oct. 28.—Worcester Automobile Club opened its indoor entertainment season Thursday night, when Colonel Fergus A. Easton told of his 2,140-mile trip through Massachusetts, New Hampshire, Vermont, Canada, and New York the past summer. He was followed in the smoketalk by Captain W. J. H. Nourse, who accompanied him a portion of the trip. This was the longest single trip taken by a Worcester club member this season. Colonel Easton told of the first motor-driven carriage he ever saw, in Glasgow, Scotland, in 1849, and of a previous 1,300-mile trip into Virginia last year in a single-cylinder Cadillac. The last trip of which he told was in a four-cylinder Stevens-Duryea. He ran 1,868 miles before he got a puncture. He found it easier to get a broken spring replaced in Canada than in Albany. He found no roads worthy his commendation outside of Massachusetts. Colonel Easton spoke highly of the information which he received in advance of his trip from the Worcester Automobile Club and the touring board of the A. A. A., both as to rates and customs necessities.

President John P. Coghlan has returned from his trip to London and other British cities. The primary object of the trip was to get the benefit of a sea voyage. C. Leslie Chamberlain, of the club's board of governors, also returned Wednesday from a trip to Europe. J. J. Quinn, of the club, and Mrs. Quinn started last week on a six weeks' tour of Great Britain.

President Arthur D. Van Dyke, of the company which makes the Hatfield buggyabout at Miamisburg, Ohio, a member of the Worcester club, last week registered the first car of that type to be registered in the State. This, with a Holsman registered by John H. Bennett, are the first motor vehicles of this type to be registered in Worcester.

Assistant Secretary Robert M. Pratt, of the Worcester club, has the past week been planting warning signs for motorists on the main route between Worcester and Springfield.

### YORK CLUB PROSPEROUS AND OPTIMISTIC.

YORK, PA., Oct. 28.—With a view to promoting interest in the York Automobile Club, the officers have announced that a series of spring tours will be held. The club is in a good financial condition, and the pastime was never more encouraging to the patrons and dealers alike, than at the present time. Announcement has been made that each one of the members of the club will be presented with an official York A. C. flag. This flag will be red and white, with the red body and white lettering, bearing this inscription: "York Automobile Club." A busy winter season is planned by the auto members, and a series of lectures along the general auto line has been suggested.

Local autoists cannot help but look with a sense of pride to the popularity of the York built "Pullman" car, which has sprung into prominence within the past year or two. Extensive improvements are being made at the local plant, and it is hoped by the promoters that next season's output will be nearly doubled.

### CONSOLIDATION OF CHICAGO AUTO CLUBS.

CHICAGO, Oct. 28.—There is a possibility that the Chicago Automobile Club and the Chicago Motor Club may be consolidated, and negotiations to this effect are in progress. Probably half of the 140 members of the Motor Club belong to the other organization, which possesses a thoroughly up-to-date clubhouse in Plymouth place and some 500 members. It is understood that the Automobile Club approached the Motor Club in regard to amalgamation, since the latter body appears to have a most energetic contingent of enthusiasts who have conducted several successful events of a competitive nature. The Motor Club will hold a special session, November 12, to vote upon the proposition.

### A. C. OF PHILA.'S FIFTH REGULARITY RUN.

PHILADELPHIA, Oct. 21.—Saturday, November 2, the fifth annual regularity run of the Automobile Club of Philadelphia for the H. Bartol Brazier cup will be decided over a cross-country course measuring something over 80 miles in length. Starting from the clubhouse at 8 A.M., the route lies out the Lancaster Pike to Paoli, across to West Chester, thence to the Schuylkill river at Phoenixville, and on through Jeffersonville and Kennett Square to the starting point. The Tours and Runs Committee, which is in charge of the affair, has laid out a time schedule which embraces the best possible time that can be made without fracturing the town and State speed laws. The driver coming nearest to the schedule will be awarded the cup. To prevent over-speeding secret checking stations will be established at various points along the route. As the schedule adopted is well within the powers of any present-day car, there will be no handicaps allowed; the usual two-minute variations allowed for arrival at checking stations will also be cut out. The affair is, to all intents and purposes, a legal speed limit run, and, although not so announced, any competitor who comes in ahead of his schedule may lay himself open to prosecution by the authorities.

### GOOD ROADS PRIZES BY MONTREAL CLUB.

MONTREAL, QUE., Oct. 28.—The directorate and several members of the Automobile Club of Canada (Montreal) journeyed this week to St. Genevieve in order to be present at the distribution of prizes offered to the land owners of that municipality through the Council of St. Genevieve in June last for the improvement of the roads in that district. The sum of \$200 was divided in three classes of prizes. The first class prizes were for roads over three arpents, second class for roads between one and three arpents, and third class prizes for roads of less than one arpent. The winners were much pleased with the result, and a large number of landowners who had not taken part stated that they were in favor of the movement and that next year they would compete.

Duncan McDonald, president of the club, remarked that the present success has not only made a better feeling between the farmers and autoists in general, but will have the effect of creating more interest next year in improving the roads.

### BUFFALO CLUB TO ADMIT WOMEN AS MEMBERS.

BUFFALO, N. Y., Oct. 21.—It has been decided by the board of governors of the Automobile Club of Buffalo that hereafter women autoists may become members of the organization. One applicant has already filed her blank for membership. There are many women in Buffalo who own automobiles and who are desirous of becoming attached to the Automobile Club.

The club now has 1,023 members, no less than 96 new members being added last Thursday afternoon. This makes the Automobile Club of Buffalo the largest local automobile organization in the country. As several applications have been received since last Thursday the directors have deemed it advisable to change the by-laws so as to admit a total membership of 2,000. At present the by-laws admit only a membership of 1,000.

### ROCHESTER CLIMB PRIZE GOES TO PACKARD.

ROCHESTER, N. Y., Oct. 28.—As a result of a protest filed by J. J. Mandery against the Franklin car which made a new record of 49 seconds for the course at the annual climb of the Rochester Automobile Club at the Dugway Hill in Penfield, October 19, Mr. Mabbett, who entered the car, has withdrawn it. This leaves G. D. B. Bonbright, with a Packard car, the winner of event No. 11. His time of 51 seconds now stands as the fastest time of the day.

## MAXIM TO BRING OUT A LINE OF ELECTRIC VEHICLES

HARTFORD, CONN., Oct. 28.—It has just developed that Hiram Percy Maxim, who quietly severed his connection with the Electric Vehicle Company as chief engineer last summer, to take up a line of work about which no details were forthcoming other than that it had to do with the automobile field, has been working on a new line of electric vehicles. Associated with him is T. W. Goodridge, and the firm title is Maxim & Goodridge, which will also be applied to the vehicles themselves. Both have been devoting their attention to the design of a new electric victoria phaeton, as pleasure vehicles will be turned out at first, though regarding future plans there is nothing definite known at the moment. So far as appearance goes, the new car does not differ perceptibly from any of the existing types, and, in fact, its builders state that such essential parts as the running gear and the like have nothing of novelty about them. But the features in an electric which determine weight suspension, transmission of the power to the driving wheels, noiselessness and simplicity are things to which special attention has been de-

voted and in the design and construction of which something quite out of the ordinary is promised, which, to quote the designers, "will be considerable of an improvement over anything of the kind thus far produced."

The first car is well under way at the present time and is expected to be complete and on the road very shortly. No announcement will be made, however, until it has been thoroughly tried out in winter service in order to prove the superiority of its design, on the culmination of which full details will be made public, together with a definite schedule of deliveries.

In the meantime it is the policy of the makers to strictly avoid any publicity regarding details, either technical or financial, until they are in a position to deliver a thoroughly tried out car on an exact schedule of dates. All plans have been very carefully laid and the designers are confident that the Maxim-Goodridge electric will find a ready market as soon as it is sufficiently developed to be placed before the public. This is the first authoritative information regarding the plans of the new concern.

### AERO CONFERENCE INTERESTS MILITARY MEN.

Owing to the presence of a large number of aeronautical experts in New York, the International Aeronautical Congress, originally planned to be held at Jamestown, took place at the Automobile Club of America, West Fifty-fourth street, last Monday and Tuesday. Representatives of the army and navy, scientists, educators, and most of the contestants in the recent race for the International Aeronautical Cup attended the gathering.

Aeronautics as applied to the military art occupied a large part of the members' attention. General James Allen, head of the United States Signal Corps, told what the United States army was doing and planning to do in the rapid building of an aeronautical branch, and Admiral C. M. Chester, of the United States navy, told what the sea branch of our national defences expected from an aerial squad. Major George O. Squires declared that the dirigible balloon was already regarded by the leaders of military thought as a thoroughly military weapon.

Each of the contestants in the international balloon race gave an account of his experiences in that event, Major Hersey in addition supplying some interesting details on the failure of the Wellman aerial expedition to start on the proposed trip to the North Pole. He declared that Mr. Wellman would repair his airship and make another attempt next summer.

Aeroplane developments were dealt with in a series of papers read before the congress by some of the most prominent men in this branch of arial navigation.

### GERMAN AERONAUT TO RECEIVE CUP MONDAY.

Next Monday evening has been fixed as the date of the annual meeting of the Aero Club of America, at the clubrooms, 12 East Forty-second street. At this meeting Oscar Erbsloeh, of the Aeronautical Club of Germany, will be presented with the Gordon Bennett Aeronautical Cup, won by the record flight of the *Pommern* from St. Louis to Asbury Park. The early date of the presentation, although official measurements had to be taken to meet a competitor's objections, is creditable to the Aero Club.

### TWO ARTISTIC COLUMBIA CATALOGS.

Two of the finest catalogs of automobiles ever issued in America are the "Electric" and "Gasoline" books issued by the Electric Vehicle Company and descriptive of Columbia automobiles. The drawings and color schemes are the work of Robert J. Wildhack, a painter with studio in Washington square, New York. Wildhack is a Westerner, hailing from interior Indiana, and he combines an artistic conception with a mechanical understanding. He is completing in spare time an automobile of his own design and build. His selection to do the new Columbia catalogue was thus an excellent choice. The frontispieces of the two books in many colors are gems which will be much sought after for framing. Wildhack's strength comes from his knowledge of detail proper to leave out. To this he gives much time and study. His execution is both quick and effective. To realize an eyebrow he employs one touch of a large brush.

CUP WINNER "POMMERN," THAT WAS INFLATED FOR A DAY.

COVER OF ELECTRIC CATALOG OF ELECTRIC VEHICLE CO.

## BRIEF ITEMS OF NEWS AND TRADE MISCELLANY

O. D. Wheeler & Company are erecting a large garage at 19 Maple street, Marlboro, Mass., which will be equipped with a fine machine shop. A complete line of supplies will be carried.

The Mitchell Motor Car Company, of New York City, has made application for membership in the New York Automobile Trade Association. This will make a total of 64 members for the association.

The Merkel Motor Company, Milwaukee, Wis., has discontinued the manufacture of automobile engines and will in the future devote the entire resources of the factory to the production of the Merkel motorcycle.

The Toronto Automobile Company, a newly organized corporation, with a capital stock of \$40,000, will erect a factory for the manufacture of autos at Port Arthur, Ont. The site has been purchased and construction of the buildings will begin at once.

The Warner Instrument Company, Beloit, Wis., makers of the Warner automobile, has instituted a department of promotion, in charge of Edgar W. Jordan, formerly advertising manager of the Shaw-Walker Company, of Muskegon, Mich.

Previous to shipping its cars to New York City for the Grand Central Palace Show, the Imperial Motor Car Company, of Williamsport, Pa., gave an inspection party to residents of that city, displaying the first five Imperials and thus giving the home people the first look at them.

Contracts for Franklin automobiles, which have been closed in eight of the principal cities west of Denver, show an increase in each instance of twenty per cent. over the number contracted for last year. This verifies to a certain extent the statements that have been made relative to a greater demand from the West.

The F. A. Brownell Motor Company, of Rochester, N. Y., capitalized at \$400,000, will commence the manufacture of automobiles in that city. The directors are F. A. Brownell, W. E. Dunn, William Deininger, George C. Whipple, Robert C. Kershner, Thomas J. Swanton, Burton H. Davy, and Clarence E. Shuster.

The capital stock of the Pittsfield Spark Coil Company, Dalton, Mass., has been increased from \$20,000 to \$100,000, and the extra \$80,000 has been paid in. The increase was made to keep pace with the company's rapidly growing business. Wm. P. Wood is the general manager of the corporation, and United States Senator W. Murray Crane, together with his brother, Zenas M. Crane, have been directors since the plant was moved from Pittsfield to Dalton.

Columbia University will offer during 1907-08 twenty evening courses specially adapted to the needs of technical and professional workers. The courses include work in applied mechanics, architecture, electricity, fine arts, industrial chemistry, mathematics, and surveying and structures. The work begins October 28 and continues twenty-five weeks. A full description of the courses may be obtained on application to the Director of Extension Teaching, Columbia University, New York City.

The Broadway Mammoth Automobile Exchange is now located in its new and absolutely fireproof building, 239-245 West Fifty-sixth street, New York City, where

it has an up-to-date salesroom and thoroughly equipped repair shop. The first and second floors are used for showrooms, the third floor for the supply department, and the fourth floor for the repair shop and body factory. Manager L. C. Jandorf has surrounded himself with a corps of able and trained assistants to make visitors welcome.

A somewhat incongruous typographical error occurred in the advertisement of the Tincher Motor Car Company, of South Bend, Ind., on page 105 of THE AUTOMOBILE of October 17. The time of the special 3-mile match race run at Milwaukee, September 21, was made to appear as "11 minutes flat." This was due to the fact that the summary of the 10-mile free-for-all event, which was also won by Allen Pirie on a Tincher, was inadvertently omitted, and the time—11 minutes—followed the summary of the 3-mile event. Eleven minutes was the time made in the 10-mile event.

One of the biggest tire contracts of the year has just been consummated between the Cadillac Motor Car Company, of Detroit, and the Hartford Rubber Works Company, Morgan & Wright, and the G & J Tire Company. This is especially significant in view of the fact that this is the fourth consecutive year that the rubber goods interest has held the contract in spite of keen competition. The terms of the contract specify that the Cadillac company will use the goods of the above companies exclusively on their 1908 product; and, moreover, that they will adopt as standard equipment on all 1908 cars the new Midgley universal rims.

One of the most complete books of its kind that has appeared is being distributed at Grand Central Palace by the American Motor Car Manufacturers' Association under the title of "Leading American Cars." It contains complete specifications of the 170 models made by the 51 members of the association, ranging from the \$500 Brush runabout to the \$7,000 Austin. The pleasure vehicles are classified separately from the commercial vehicles. The book contains a brief history of the association, an index of the cars described, all the important records, and a number of important firsts in automobiling, such as the first race winner, the first tour, and hill climb, and similar events.

### RECENT BUSINESS CHANGES.

The Linkroum Automobile Company, of Newark, N. J., succeeds the Linkroum-Smelter Automobile Company, owing to the recent death of L. W. Smelser. S. H. Stern, formerly assistant manager of the Michelin Tire Company of America, is a new member of the company. The Linkroum Company will have the exclusive selling rights of the Lozier line in Central New Jersey.

The garage business of the Palmer & Singer Mfg. Co., of New York City, distributors of the Matheson, is to be conducted in the future by the Knickerbocker Garage Company. The officers of the latter company are the same as those of the former. The Knickerbocker Company will take over the garage business of the Palmer & Singer Mfg. Co. when the latter moves into its new five-story building, in about two weeks. Practically every owner of a Matheson car in New York, as well as many other autoists, have reserved space in the new garage.

### NEW AGENCIES ESTABLISHED.

N. L. Merwin, of Amsterdam, N. Y., has taken the Lozier line for Fulton and Montgomery counties, in the State of New York.

J. S. Russell, of New Orleans, has contracted for the Glide agency, and will organize a company at once to handle the Glide line in the State of Louisiana.

Owing to the great demand for the Jones speedometer in France, the Jones Speedometer Company has opened a branch house at 88 Boulevard de Courcelles, Paris, in charge of Rudolph Simonetta.

Mr. Dilley, of Los Angeles, Cal., one of the largest auto dealers in that State, has taken over the Pacific Coast representation of the Autocar. Arrangements were concluded when Mr. Dilley visited the Autocar factory at Ardmore, Pa., last week.

Arrangements have been made for the sale of Brush runabouts in Illinois by the Pardee Motor Company, of 1229 Michigan avenue, Chicago. Fred J. Pardee, a pioneer dealer and one of the oldest members of the Chicago automobile trade, is at the head of the company.

The new Philadelphia branch of the Firestone Rubber Company, located at 256 North Broad street, will open for business on November 1. The establishment, which has an area of 14,250 square feet and is complete with all modern facilities for the application and repair of tires, will be in charge of W. R. Walton.

Sales Manager W. C. Metzger, of the Cadillac Company, gives information concerning the appointing of G. J. Grossman as New York agent for the Cadillac. Mr. Grossman is the owner of the big garage at White Plains, N. Y., claimed to be the largest in the country. It has 21,600 square feet of space on one floor.

November 1 the Babcock Electric Carriage Company will open a branch house in New York City at 1591 Broadway, corner Forty-eighth street. H. E. Wagner, formerly connected with Wyckoff, Church & Partridge, and who had charge of the Babcock line with that house, has been appointed eastern sales manager with headquarters at the new branch.

Among European products recently introduced to the American trade are the patent non-skidding rivets and the Edco spark plug, manufactured by Edouard Dubied & Company, of Couvert, Switzerland, and the chrome leather made by Cavernier & Quezin, of Paris. These firms are represented in the United States by Chas. Dien, 43-45 West Thirty-fourth street, New York City, who has already closed several good contracts with American manufacturers for their use on 1908 products. Mr. Dien is also the American representative of the Touring Club of France.

### PERSONAL TRADE MENTION.

Vice-President H. E. Coffin, of the E. R. Thomas Detroit Company, will sail for Europe November 6 for a two months' study of trade conditions and development in England, France, and Italy.

J. C. Matlack has been elected vice-president and general manager of the Michelin Tire Company of America. C. C. Harbridge, who is well known in the selling trade, is to have the managership of the Chicago branch.

C. P. Brown, formerly of the Motor Car Equipment Company, of New York City, has been appointed manager of the Motor Mart Sales Company, factory distributors of automobile accessories, with headquarters in the Motor Mart, Broadway and Sixty-second street, New York City.

Clarence A. Saffle has been appointed Pacific Coast representative of the Warner Instrument Company, of Beloit, Wis., with headquarters at San Francisco, and with California, Washington, and Oregon as territory. Mr. Saffle was formerly connected with the Underwood Typewriter Company.

Ben Blumenthal, proprietor of the West End Auto Palace, was elected a director of the New York Automobile Trade Association, at the last meeting of the board of directors of that organization, to succeed Carlton P. Mabley, who resigned from the directorate because he is no longer actively engaged in the sale or storage of autos.

T. F. Smith will succeed A. F. Chase as manager of the Maxwell-Briscoe Chase Company, Chicago, Ill., and George Holden, of Detroit, will succeed A. S. Johnson, secretary of the above firm. Mr. Smith comes from the National Cash Register Company, having resigned as sales manager of the Chicago branch to accept his present position.

M. C. Krarup, the well-known writer on automobile subjects, has become interested with the firm of John Crowley & Company, 120 Liberty street, New York, in the importation of crucible nickel and chrome-nickel steels and forgings, from the Krefelder Stahlwerk, of Krefeld, Germany, and will take charge of the automobile end.

Percy S. Cradock, of the firm of George Cradock & Company, of Wakefield, England, manufacturers and specialists of fine quality alloy steels for the automobile trade, is in New York for the purpose of appointing an agent for his firm's products. Mr. Cradock is stopping at the Holland House and can be seen until November 6 by appointment.

Welton H. Flynn has been appointed assistant sales manager of the Acme Motor Car Company, of Reading, Pa., and will be in charge of the eastern territory. In securing the services of Mr. Flynn the Acme company obtains the services of a popular representative. He will make his headquarters with the New York agents, J. B. Brewster & Company, Seventh avenue and Forty-ninth street, New York City.

Directors Tischlein and Gerlach, of the Continental Caoutchouc Company, have arrived in New York from Hanover Germany, and have been in attendance at the Grand Central Palace automobile show. They will return to Europe at the end of this week. Manager Gilbert, of the American branch of the Continental Company, is receiving congratulations on the showing of the business done in this country.

Recent changes in the E. R. Thomas Detroit Company, of Detroit, Mich., makers of the Thomas Detroit, include the appointment of John G. Utz as chief engineer, with G. G. Behn as his assistant. Mr. Behn is well known in the trade, having been associated with the industry prior to entering Cornell University in 1898, and after his graduation in 1902. Mr. Behn has had a wide practical as well as theoretical experience in all branches of auto construction.

**FANNING MAKES CHANGE.**

Frank J. Fanning, long connected with the Haynes Automobile Company, of Kokomo, Ind., as sales manager, has resigned to accept a partnership with James Levy, of Chicago, agent for the Autocar and

other cars. Mr. Fanning has been succeeded by C. B. Warren, who has for a long time been manager of the New York agency of the Haynes company. Mr. Warren, during his term of office in New York, has been most active in his position, having disposed of more Haynes cars in New York than were ever disposed of by a former manager, and also having won for the Haynes sterling honors in all events open to him in New York. Mr. Warren will be located at Kokomo, but will have general charge of all the agencies.

**"WON'T SLIP."**

They hold their own; they hold the road,  
And at no curve need they be slowed;  
Upon the earth they keep their grip—  
And Bailey Tread Tires won't slip.

They're Tires that hold the right o' way.  
They've come to go and come to "stay"  
And while you go the merriest clip  
The Bailey Tread Tires won't slip.

They're "knobby" Tires that stand all strain.  
The "Rubber Studs" are safe and sane;  
The stretch of ice you need not skip  
For Bailey Tread Tires won't slip.

For Auto, Auto-BI or BIke,  
They lead in speed on track and plke.  
They neither ravel, rend nor rip,  
And Bailey Tread Tires won't slip.

They "corner" all the turns with ease;  
No "heart in mouth" if you have these;  
No sudden short turn brings a tip  
For Bailey Tread Tires won't slip.

They are not skidders that skidoo.  
All roads are pleasure roads to you;  
The "Won't Slip" Tread says every lip,  
Is rightly named "Won't Slip." —(A. W. B.)

**NEW TRADE PUBLICATIONS.**

Ejector mufflers manufactured by the Motor & Manufacturing Works Company, Geneva, N. Y., are illustrated and described in a new sixteen-page handbook just issued.

A detailed route card showing the best road from Chicago to South Bend, Ind., has been issued by the Studebaker Automobile Company, of South Bend, Ind. The journey is treated in both eastern and western directions.

Descriptive of the various models of the Schacht Auto-Runabout, an automobile of the improved buggy type, the Schacht Manufacturing Company, of Cincinnati, O., has issued an attractive illustrated catalogue.

Scenes on the road and peeps into the showroom elbow one another in Number 7 of the *Reo Echo*, devoted to the interests of R. M. Owen & Company. Editor Gogarn presents an aftermath of the Glidden Tour, in which the Reos were well to the fore, and puts forth a sketch of his company's features for 1908.

Bulletin Fourteen from the White Company, Cleveland, deals with the most important contests entered with conspicuous success by White steamers. Prominent among them are the Glidden tour, the London town carriage test, the Harrisburg endurance run, the Cleveland hill climb, the Wilkes-Barre hill climb, and a number of prominent events abroad. The booklet, which is illustrated and printed in colors, contains a map of the Glidden tour route.

**INFORMATION FOR BUYERS.**

**Brass Specialties.**—The G. W. Murphy Company, Merrimac, Mass., are manufacturing an extensive line of brass specialties specially designed for automobile use, and among which they call special attention to their assortment of door handles. These

are shown, together with their corresponding fittings, in a wide variety of styles in polished brass, nickel or silver-plate, and are made either with slotted screw washers, flat washers or escutcheon plates. The plated finishes are of the Murphy standard plate, and are guaranteed by the makers to wear. The designs listed are largely ex-

ONE OF THE MURPHY DOOR HANDLES.

clusive with this house, and all door handles are guaranteed to have perfectly fitted washers and true shanks. In addition to door handles they also make a specialty of the Murphy curtain fasteners, which have been designed especially to meet the requirements of the automobile and motor boat. They are covered by patents, and it is the claim of the makers that they will not release the curtains under any stress of weather or vibration.

**U. & H. Magnetos.**—The J. S. Bretz Company, Times Building, New York City, who are agents for the F. & S. annular ball-bearings and Hartford universal joints, have taken the U. S. agency of a new high-tension magneto made by Unterberg & Helmle, Karlsruhe, Germany. In general

UNTERBERG & HELMLE MAGNETO.

construction and operation it is similar to the standard types, but has an unusual feature in the shape of an easy starting device. This consists of an arrangement whereby the armature may be given part of a turn at high speed, producing a hot spark irrespective of the position at which the interruptor is set to operate. During this partial revolution the speed of the armature is entirely independent of the rate at which it is turned by the crankshaft of the motor while in service. The device is in operation only while the motor is being started, being automatically disengaged. The spark is automatically retarded by this starting device, which makes it unnecessary either to spin the motor or resort to the compression relief. The armature differs from standard types in having both the condenser and interruptor mounted in a separate housing. The spark gap is of improved construction, and is provided with mica windows. Both low and high-tension types are made for two, three, four or six cylinders, as well as an oscillating type for stationary use.

No. 19

## American Industry Challenges World: A. L. A. M. SHOW CONVINCINGLY ASTOUNDS

THE A. L. A. M. show is a distinct, comprehensive, and overwhelming triumph of the American manufacturers of automobiles, challenging in unmistakable manner unbiased and equal comparison with the product of the leading European makers, who possessed advantages gained through being first in the field by several years. The exhibition in Madison Square Garden, which opened expectantly on Saturday night, November 2, and will close brilliantly on Saturday evening next, is a revelation even to those who have followed the industry from its earliest stages and watched the gradual development and betterment of automobiles in this country. While one might be inclined to question the continued extraordinary demand—a steady demand is assured—for the output of such a substantial number of concerns bidding principally for *de luxe* patronage, he must realize that the highest types of cars are now available, American-made, to those who can afford these luxurious vehicles with gorgeously finished bodies and sturdy, reliable motors, capable of long journeys, the climbing of mountains, and progress over roads not deserving of the name.

And all of this in less than a decade!

Of course, there will always be those who prefer to buy something from abroad, and, while admitting the excellence of European cars, one fails to comprehend why the patriotic and discerning American should longer select his high-priced automobile on the other side of the

HOW THE STAIRWAYS WERE DIVIDED.

salt pond when he can do equally well in quality, and much better from a financial point of view, by buying at home.

Once upon a time a couple of makes stood out prominently, and while their owners still swear by them it is possible to pick any one of a score and more of American cars and obtain a commensurate return for the money invested. The popular priced car does not have much of an innings in the Garden, and, while there

is provision for the man of moderate means, the bulk of the show is devoted to those who want the very best and are willing to pay for it. In fact, it is a display of highest-grade automobiles, and one which will astound even the man who in the past could see nothing worth having except an imported vehicle.

Of course, the American makers are proud of what they are presenting in the big Garden, and they have good reason for feeling elated and confident and satisfied, for their 1908 models will meet the wishes of the most fastidious.

It may be that the recent flurry in Wall street, instead of curing the broker of his automobile habits—something well nigh impossible after he has become wedded to the use of a car—has caused him to figure a little more economically, which means that 45 per cent. duty is an item which he has in mind to blue-pencil. Advising him to take a look at the Garden array is an act for which he is likely to feel grateful, in view of the financial bumps over which many have traveled recently with deflated tires and benumbed shock absorbers.

To the double music of the sonorous telharmonium and the more flexible tones of the Garden band, the thousands have noted that the licensed cars have been not only embellished exteriorly, but inwardly the vital parts have been perfected in vast degree until any amount of mileage is available with sane use and care, for even engines of automobiles require looking after like any other piece of machinery, and that which the automobile accomplishes nowadays often approaches the phenomenal.

In all the 39 different makes of pleasure cars, 9 of pleasure electrics, 12 of commercial vehicles, and 14 of motorcycles, which go to make up the show as a whole, there is entirely lacking the element of freak design once so prominent. And what is even more noticeable is the high standard of finish and equipment represented by the bodies of the cars, as well as their uniformly excellent design, patterned after the straight-line type.

Though the show is, in the main, one of high-grade cars representing the most advanced degree of the builders' skill and listing at correspondingly high prices, there is much to attract those whose interest is most keen in the lesser priced vehicle, and the range of prices is very wide indeed. Beginning with the small twin-cylinder, air-cooled and friction-driven Waltham at \$600 in the runabout class, the single-cylinder Cadillac at \$850, and the new Buick four-cylinder runabout at the same price, which is attracting such an unusual amount of attention, it is but a step to the \$1,000 to \$2,000 class of touring cars, which are represented by no less than five examples, of which several have all the attributes of many of the higher-priced cars in the shape of four-cylinder vertical engines, sliding change-speed gears, long wheelbase and large tires.

### M. J. BUDLONG ELECTED A. L. A. M. MANAGER.

Thirty of the thirty-one members of the Association of Licensed Automobile Manufacturers attended the annual meeting, held Wednesday afternoon, at the association headquarters, and elected Milton J. Budlong as general manager, to succeed E. H. Cutler, who found it impossible to continue in office because of his recently increased duties as president of the Knox Automobile Company, of Springfield, Mass. Charles Clifton was re-elected president; H. H. Franklin, as treasurer; and L. H. Kittridge, as secretary. Thomas Henderson was selected as first vice-president, taking the place of F. L. Smith on the executive committee, which will also include Charles Clifton, W. E. Metzger, S. T. Davis, Jr., and George H. Day. Mr. Smith asked to be relieved, owing to his inability to give time from his duties as head of the Oldsmobile Company to attend the meetings in New York City.

Mr. Budlong, who recently retired from the presidency of the Electric Vehicle Company, is a well-known figure in the automobile industry, personally popular, and possesses well proven executive ability. His selection is commented upon most favorably.

Mr. Cutler, in retiring, made a few brief remarks, in the course of which he thanked the members for their hearty co-operation and support extended him during his term of office, and commended Mr. Budlong as a capable successor.

### MOTOR AND ACCESSORY MFRS. ELECT DIRECTORS.

Some sixty members attended the annual meeting of the Motor and Accessory Manufacturers, held at the Hotel Astor, Wednesday morning. The president's report showed since the formation in Cleveland, February 11, 1904, a steady increase in membership. In 1904 there were 94 members; 1905, 130 members; 1906, 173 members; and at the present time, 192 members. The treasurer's report indicated an ample balance in the treasury.

These were the directors elected to serve for three years: W. S. Gorton, Standard Welding Co.; H. S. White, Shelby Steel Tube Co.; P. S. Steenstrup, Hyatt Roller Bearing Co.; H. E. Raymond, B. F. Goodrich Co.

Elected to serve for two years: C. E. Whitney, Whitney Mfg. Co.; D. J. Post, Veeder Mfg. Co.; C. T. Byrne, Byrne, Kingston & Co.; H. W. Chapin, Brown-Lipe Co.

Elected to serve for one year: E. S. Fretz, Light Mfg. & Foundry Co.; H. T. Dunn, Fisk Rubber Co.; F. E. Castle, Gray & Davis; L. M. Wainwright, Diamond Chain & Mfg. Co.

Following the adjournment to the annual meeting, the board of directors met and organized by electing the following officers: President, H. S. White; first vice-president, H. E. Raymond; second vice-president, H. T. Dunn; third vice-president, F. E. Castle; treasurer, W. S. Gorton; secretary, Peter S. Steenstrup.

A sanction was granted to the Philadelphia Automobile Trade Association for a show, to be held in Philadelphia next week.

TAKING IN THE CARS AT THE GARDEN'S REAR ENTRANCE.

LONG before the manufacture of automobiles in this country had arrived at a stage where its importance was sufficient to dignify it by the title of industry, those far-seeing makers who were then pinning their faith to the future of the new method of transportation realized the need of co-operative effort if the many obstacles that then confronted them were to be successfully met and overcome. They fully realized that, in addition to the task of evolving the perfect automobile, and that time is but a very few years back, there were so many other things to be accomplished that no single maker could possibly attempt to cope with them all. The result was the formation of the Association of Licensed Automobile Manufacturers, more familiarly known as the Licensed Association and the "Selden interests."

When first the manufacturers who go to make up the membership of this association came together they practically represented what was the nucleus of the entire American automobile industry of to-day, but their combined product formed as motley an array of self-moving vehicles, termed automobiles, as can only be found within the four walls of a museum at the present writing. Development has been so rapid, and yet so solid and permanent, that it is hardly conceivable, even to those who have been most closely identified with the automobile movement during that time, that the result as now spread forth in the Garden can be the work of but three or four years. It positively seems years ago that the outlandish and lumbering productions of 1903 and 1904 were gazed upon with rapture and no little patriotic pride at the self-same spaces that many of them now occupy, as being representative of the highest ideals of American automobile construction. Think for a moment of the Winton of those days and compare its two tremendous horizontal cylinders that completely filled the chassis frame from side to side, and almost from end to end, with the graceful and perfected six-cylinder construction of the same car which to-day is being exhibited within less than fifty feet of where it was accustomed to hold forth in earlier times.

What of the little one-lungers with the curved dash that made the name Oldsmobile a byword the world over? It is not hard to picture the array of them that formerly filled the exhibit of this concern and which held the attention of a very large part of the entire attendance during show week, for they were the first examples of the popular-priced automobile. But it is next to impossible to reconcile the idea of the exquisite Packard creation, which now tenants almost the same space that it has held forth at for years, with the tremendous single-cylindered affair that did duty as its predecessor at the same stand. It represents a process of evolution that would puzzle a Darwin. Then there was the Stearns, which had less engine in more space, and more parts than were impossible to get at without the aid of a pit than could be found on a season's output of the same make of cars to-day. At that time the Elmore was a wire-wheeler perched aloft on a sort of hermaphrodite running-gear, with its power plant of the two-cylinder type somewhat in the position of Mahomet's coffin,

suspended in an inverted position underneath the seat.

Wherever one looks around the Garden there are the old familiar names and the familiar faces that make the Garden show somewhat akin to a family reunion to the old-timer. Who would recognize in the Thomas or the Haynes of to-day their horizontal-engined, short-wheelbased prototypes of but a few short years ago had he not been able to follow the different steps of development that have taken place in the interim? Then there was the Pierce "Motorette," and its bigger brother of a year or so later, the Pierce "Starhope"—cars which had the cardinal virtue of being able to run in high degree, but the former of which, at least, reminded one more of a gatling gun. From those models to the Pierce "Great Arrow" and the Pierce "Big" and "Little" sixes is a far cry indeed.

WHITE STEAM CARS WERE WELL AND EFFECTIVELY PLACED.

But even more so is a comparison of the one and two-lunger Knoxes and their ponderous parts with those of their refined successors that bear about as much resemblance to their honored forbears as an ice wagon does to a racing sulky. And so it goes down through the list; Franklin air-cooling is still the same air-cooling of those days, but the refinement accomplished seems like the work of a dozen years.

Here are still the same numerous representatives of the Pope family, and it will be remembered that the Pope cars were among the very first to adopt forms of construction that are now recognized as standard, such as the four-cylinder vertical motor placed forward under the bonnet. The early annals of American automobile racing are inseparable from the Peerless, and its rapid development to a state of perfection recalls the service rendered the industry in its infancy by the racing game. No matter what part of the Garden the visitor finds himself in he sees cars that have graced the same or neighboring spaces ever since the great arena has housed the automobile show. The Locomobile, which in the early days had to live down the name borne by its ill-fated predecessor of the tea-kettle type of steamer; the Cadillac, first, last and all the time, the undying advocate of single-cylinder economy and simplicity; the Northern, Lozier and Matheson, all of which took part in the early struggle toward the goal.

In this connection the show houses one of the most notable examples of well-directed and persevering effort that any industry can boast of—that of the White. When steam was practically down and out, to revert to current slang, the builders of the White maintained their faith in it and through their determination and skill have shown that it is far more applicable to the automobile than its first users ever dreamed of. The result, as shown by their exhibit, is a monument to the name.

Taken all in all, the show is representative of the acme of the American automobile industry, and one cannot fail to be struck by the reflection: Why should an American think of buying a foreign-made car?

POWER-PLANT AND ELECTRIC TRANSMISSION OF THE COLUMBIA.

By CHARLES B. HAYWARD.

It only requires a little observation and study to show, despite the fact that a high degree of standardization has been approached by American automobile builders, that all motors are not alike by any means. They differ, not alone where details are concerned, but even with regard to many features that must be considered as of greater importance than merely a change of arrangement. The latter essential is capable of so many changes that it is quite evident there are a great many ways of accomplishing the same end where the internal combustion motor is concerned.

To begin with there is more diversity of opinion apparent now regarding the matter of cylinder casting than there was two or three years ago, when it was confidently predicted by the advocates of one method or the other that their school would predominate in the near future. Those who were advocates of one type or another at that time have remained loyal to their convictions, so that there are just as many instances of cylinders cast in pairs and cast separately as there have been. The same thing is true of the various methods of valve placing and operation. The practice of making a one-piece casting of the four cylinders has found a new recruit in the Thomas town car, though this is a special design that embodies numerous other features of merit, placing it practically in a class by itself.

Newcomers to the ranks of the cast-in-pairs advocates are to be found in the Selden; other prominent instances of this being Locomobile, Royal Tourist, Lozier, Peerless, Columbia, Winton, Oldsmobile, Stearns, Thomas Detroit, Pope-Toledo, Studebaker, Packard and Haynes light cars, while those upholding the plan of casting the cylinders individually are to be found in Pierce, Haynes, Apperson, Franklin, Corbin, Knox, Thomas Flyer, Cadillac, Stevens-Duryea, Autocar, Matheson, and Elmore, the latter making as short a motor with independently cast cylinders as the average four-cycle type with twin castings. The Northern and the Waltham display the only in-

stances of the two-cylinder horizontal type to be found show, though they differ in all other respects.

#### Some New Motors at the Show.

It might be thought, owing to the membership of the exhibiting association being limited and designs as a whole having reached a very marked degree of standardization, that there would seldom be any really new motors to chronicle at the annual shows. Naturally, new in this connection must be regarded as indicating more the fact that the makers of the motors are newcomers in the market rather than that the designs are particularly novel, but even this finds one or two striking exceptions, such as the Franklin air-cooled motor and the new Knox water-cooled motor, a complete description of which appears elsewhere in this issue. While still adhering to those standards of design long familiar on the Franklin motor, the latter has been practically redesigned and with its spherical combustion chambers and concentric valves, the arrangement of which has been very cleverly worked out, it embodies a great many features of interest to the technically minded visitor with an eye to what is new in the way of motor design and construction.

This also applies to the new water-cooled Knox motor, in that the latter is among the first, if not actually a pioneer, in the readoption of a principle long utilized in the building of stationary gas engines—that of making the cylinder heads separable. The design is of unusual interest, as by careful study the disadvantages which caused this form of construction to be abandoned at the outset in the building of automobile motors have been completely overcome and all the advantages it affords gained.

The Corbin water-cooled motor is another newcomer that is of interest, and the first thing about it to strike the observant eye is the peculiar shape of the lower half of the crankcase or oil pan, which has been designed to act as a shield for the flywheel in the rear and has been extended forward sufficiently to protect the fan pulley and timing gears from below. The cylinders are separately cast units with the valves placed all on the left-hand side and operated by the direct thrust method from a single camshaft. The oil and water pumps are also on this side and are actuated by a separate shaft driven through spur gearing from the camshaft, while the inlet manifold is carried between the central pair of cylinders and the carburetor located on the other side of the motor. The outlet from the gear-driven centrifugal pump is also carried between the cylinders to the opposite side. Both inlet and exhaust manifolds are held in place by the same yokes, making them easy to dismount. Particular attention has been paid to accessibility, unusually large hand holes being provided in the sides of the crankcase—in fact, this is practically all open when the plates have been removed.

The new Lozier four-cylinder motor has a combined pan

WORKING SIDE OF THE NEW 25-HORSEPOWER SELDEN MOTOR.

MERITORIOUS FEATURES OF THE THOMAS TOWN CAR MOTOR.

FEATURES OF THE NEW CORBIN WATER-COOLED MOTOR.

and crankcase which represents an extremely creditable example of aluminum casting.

With the exception of the fact that the cylinders are cast in pairs, much of the foregoing description may be said to apply to the new four-cylinder Selden motor, which is shown in two sizes, a 4 1-4 by 4 1-2-inch, rated at 28 horsepower,

THE HIGH-POWERED SIX-CYLINDER PEERLESS WITH DUAL IGNITION.

and a 5 1-4 by 6-inch motor, rated at 45 horsepower under the recently adopted formula. The centrifugal pump and magneto are both driven from an independent shaft on the right-hand side of the motor, which is also the valve side. On the smaller motor a mount is provided for a magneto, but on the latter the generator itself forms a regular part of the equipment. The low-tension timer is mounted vertically on

SIMPLICITY OF THE INLET MANIFOLD OF THE NEW LOZIER "SIX."

SHADOWGRAPH OF THE NEW FRANKLIN AIR-COOLED MOTOR.

a short shaft located at the rear of the motor and driven from the end of the camshaft. The exhaust manifold is given a slight upward bend, and the outlet, which is located in the center, faces toward the motor, the connection to the muffler being carried across and down.

#### Compactness Guiding Star of Designer.

It is when he comes to consider the power plant of the new Thomas town-car that the observer finds a great deal of food for reflection. It is quite evident that compactness has been the guiding star of the designer throughout, and that this has been amply achieved is apparent at a glance, as its 20-horsepower motor could almost be carried off under one's arm. The cylinders are cast as a single unit, and the most noticeable thing about this construction is the fact that the exhaust manifold has been made an integral part of the motor. It is also provided with cooling flanges.

To one familiar with foreign practice, it is plain that there has been little attempt at originality, but that the designer has culled the best from a number of standard French designs and embodied the results in this motor. For instance, it is easy to recognize the Renault type of flywheel, the C. G. V. single-piece casting, the Brasier combined tank and radiator, Renault type of thermo-syphon circulation, and the latter is a particularly noticeable feature which adds materially to the neat appearance of the motor as a whole, as there is no water-piping in evidence, with the exception of the radiator connections, while all the wiring is encased except right at the plugs, and the magneto can be lifted off for inspection, merely by loosening a thumb-screw. The motor as a whole is carried on a sort of oscillating three-point suspension, which has been very ingeniously worked out, and carried to a successful result.

DEVELOPMENT OF THE OLDSMOBILE "SINGLE" OF FORMER DAYS

LOCOMOBILE MAGNETO, CARBURETER AND CIRCULATING PUMP

SHOWING THE LOZIER CRANKCASE CASTING AND VALVE COVERS.

That there are not a great many novel features to be looked for in the new sixes is not difficult to learn, for, except in such cases as have the subject of special design, the majority of the six-cylinder motors do not differ greatly from the fours turned out by the same makers. Though so much has been said and written of the six-cylinder motor as being something quite new during the past season, it only requires a moment's reflection to recall the fact that this is far from being the case. There have been six-cylinder racing cars for three years past and six-cylinder stock cars for fully two years past, one maker alone claiming to have several hundred of them on the road. The Stevens-Duryea "Big Six" dates back to the 1905 shows, and the Pierce Arrow to the 1906 A. A. A. tour, while the Thomas six-cylinder racing car was one of the first of its kind to be seen in this country, and the Franklin air-cooled six has been a stock car for two seasons. So it seems the six is not an extreme novelty by any means, but the increased demand for this type of motor is reflected in the increased number shown at the Garden, among which such newcomers as the Pierce "Little Six" and the Winton "Sixteen Six" are of special design, the latter being the sole representative of the Winton line, which this year is confined to this type of car.

But, as a general rule, designers have adhered closely to the standards represented by their productions of the four-cylinder type in evolving the six-cylinder motor—so much so as to lead one to the conclusion, as has been frequently overheard at the Garden, that "it is merely a case of sticking on another pair." For instance, the Peerless six-cylinder motor is characterized by cylinders cast in pairs, oppositely disposed valves actuated by the direct thrust method from separate camshafts and other features that have long been identified with Peerless construction. In the same manner

the new Thomas six-cylinder has separately cast cylinders, which is also true of the Pierce "Little Six," while the new Stearns six is true to its four-cylinder prototype.

This practice of merely adding another pair of cylinders to the existing type of motor, which many of the makers have found it expedient to adopt as the easiest and most

COMBINED POWER-PLANT AND SPEED GEAR OF THE NORTHERN

economical method of bringing out a six-cylinder model, has naturally led to the production of unusually powerful cars, despite their extremely conservative official ratings, which are very misleading—or at least they would be if any of the salesmen at the exhibits were content to have the visitor depart with the impression that the official and the actual rating were one and the same thing.

THREE-POINT SUSPENSION OF THE STEVENS-DURYEA "LITTLE" SIX.

EQUALIZED INLET MANIFOLD OF THE NEW PIERCE SIX-CYLINDER

LOW-HUNG POWER-PLANT OF THE NEW THOMAS SIX-CYLINDER.

For instance, the new Stearns six, which is admittedly a replica of the well-known four of this make, with the addition of an extra pair of cylinders, was rated by the makers at 90 horsepower when first brought out, and its cylinder dimensions of 5 3-8 by 5 7-8 inches amply justify this, though its A. L. A. M. rating is but 69.3 horsepower. The Peerless 5 7-8 by 5 1-2-inch six-cylinder is rated at 57 horsepower, evidently an error, and the Thomas at 72.6, from which it will be apparent that designers generally have seemingly lost sight of the chief reason for building six-cylinder motors—that of gaining smoother torque and greater flexibility—and have taken to the building of ponderous motors for which there can naturally only be a limited demand at the best. It is in these examples of excessive weight and power, which mean correspondingly high tire and fuel expense, that the advocate of the four-cylinder type finds his best argument against the practice of adding another couple to the present standard, which has certainly been brought to a high degree of efficiency and smooth running.

#### Sixes Are Larger and Very Powerful.

If the six-cylinder is to be the coming type that will ultimately sweep all before it, as some of its most ardent advocates are now of the opinion, such cars as the Stevens-Duryea and the Pierce "Little" Sixes represent steps in the right direction. That six-cylinder cars of 70 to 90 horsepower, or any other design of such high power, do not represent an ultimate standard is a statement that calls for no refutation, and the fact that makers will only build limited numbers of such cars shows that they are of the same opinion. It is merely a case of taking advantage of a demand that is making itself felt at the moment. Firms like the builders of the Packard, Cadillac, Columbia, Matheson, Knox, Corbin, Autocar and some others have remained steadfast to their allegiance to the four-cylinder type.

When it comes to the matter of motor accessories there is one trend that is very noticeable, and that is toward the adoption of the magneto. In fact, from a much maligned object, the value of which was very slightly regarded by the American maker but a very few years ago, the magneto has come to be a standard feature of motor equipment to such an extent that it is not lacking on any but the lowest-priced cars, and there merely owing to the fact that the list price of the car does not permit of its inclusion, though it is almost invariably offered as an extra, and motor design has been modified to facilitate its fitting in practically every instance. One exception to this is to be found in the case of the two-cycle Elmore, on which the Atwater-Kent ignition apparatus used in connection with dry cells as the source of current, has been adopted as the regular equipment.

Where this essential is concerned, technical opinion appears to be pretty well divided regarding the merits of the self-contained type of high-tension magneto, such as the Bosch, and the high-tension with coil type, such as the Eise-mann, though in at least one instance the latter is fitted as a regular part of the equipment and the purchaser is given an option of the Bosch where preferred, this being on the Pope-Toledo. Low-tension ignition can hardly be said to have made any perceptible inroads into the ranks of those advocating the high-tension type, as such cars as the Locomobile, employing its own type of magneto, the Matheson, Studebaker and Columbia are still the most prominent up-holders of make-and-break ignition.

Where the carbureter is concerned, the chief change to be noticed is in the adoption of the Venturi tube type of Holley make on the Winton, and the adoption of a water-jacketed type in connection with a hydraulic governor on the new Lozier motor, similar to that used for three years past on the Packard and still consistently adhered to. There is another striking feature about carbureter practice, and that is that the average maker has come to the conclusion that he can buy a better carbureter than he can turn out in his own works, and, in consequence, a surprising number of the old line makers have given up producing this essential in their own factories and now purchase their carbureters complete, ready to be fitted to the cars. There is little or no change where the remaining motor accessories are considered, with the exception of the lubrication, in which there is a tendency manifest to reduce this to an extreme of simplicity, the oil being circulated by a pump and returned to a well, where it is filtered and again pumped through the system, thus eliminating the numerous small oil feeds which mean added complication. Either in this form, or something akin to it, are the lubricating systems of the Pierce, Packard and Lozier, all three being distinguished by their simplicity. Though not exactly an accessory, valve mechanism covers are a new adjunct and may be mentioned under this head; they are employed on the new Winton and Lozier motors.

#### Some Concluding General Observations.

While the past season has not been marked by defections from the ranks of advocates of air-cooling, those of water-cooling have gained two new partial recruits in the shape of the Corbin and the Knox, both of these motors, as already mentioned, being of considerable interest. A review of the entire show reveals but four different makers, if the motor-cycles be omitted, namely: Franklin, Knox, Corbin and Waltham, although the latter are also showing a water-cooled car having a two-cylinder horizontal type of motor, which is merely a runabout body mounted on the standard Waltham two-cylinder delivery chassis for 1908.

The White steamers are also the sole representatives of their class, and as such hardly come within the purview of any review of tendencies having to do with the internal combustion motor, of which the show as a whole affords so many striking examples of perfected types.

FAMILIAR LINES OF THE ROYAL-TOURIST MOTOR FOR 1908.

BY W. F. BRADLEY

CONSIDERED numerically, the display of commercial vehicles at the A. L. A. M. show has not assumed very large proportions. Gasoline is represented by not more than half a dozen firms, and constructors of electric commercial vehicles in several cases only show one or two examples of the numerous types produced by them. One concern had the distinction of holding a vehicleless stand, adorned only by a group of salesmen, while the show space of several other firms provided ample accommodation for spectators.

Most conspicuous of all, on account of its great size, is the Alden-Sampson gas-electric road train, consisting of a four-cylinder gasoline engine coupled up to a dynamo, the current produced being transmitted to the tractor and a series of trailers. The distinguishing feature of the train is that each of the six-wheel trailers is controlled and steered from the tractor, every vehicle following exactly in the track of its predecessor. A full train of five or six trailers, each one carrying a load of five tons, can thus be handled by one man.

In the heavy-load gasoline vehicle class Hewitt stands alone with a powerfully constructed five-ton truck, shown in bare chassis and with a stake body. The power plant, which is carried forward under the driver's seat, where it is easily accessible, consists of a four-cylinder engine with cylinders cast in pairs, developing 32 horsepower at 1,000 revolutions. Having been specially designed for this class of work, the engine has naturally been made as accessible as possible, and constructed so that any part may be inspected without dismantling the whole. As an example, large inspection plates not only admit of a complete examination of the main bearings, but allow the pistons to be removed without dismantling the engine. The valves are all on one side, flat seated and much larger than is usual in automobile practice, and are operated by a one-piece nickel-steel camshaft. On the opposite side of the engine is a high-tension gear-driven Bosch magneto, and the automatic carbureter, both easily accessible, the magneto being dismantlable in a few minutes. Fuel supply is by pressure feed from a large tank hung to the side frame, to an auxiliary tank forward and slightly above the level of the engine. From here the flow to the carbureter is by gravity.

Transmission is of the planetary type, with nickel-steel gears and shaft; the improved control, by which three speeds forward

and reverse are obtained, is designed to make it impossible to put in one speed until the other is automatically thrown out. Final drive is by means of heavy side chains from countershaft to the rear wheels, the countershaft with bevel gear and differential being mounted on Timken roller bearings. The economical speed claimed for the truck is seven to nine miles an hour. The maximum speed when running light is fifteen miles an hour.

In addition to their heavy vehicle, the Hewitt Motor Company displays a single-cylinder 10-12-horsepower light delivery wagon, with closed body, guaranteed to carry loads of 1,000 to 1,500 pounds.

The H. H. Franklin Company's only representative in the commercial class is a light stake wagon driven by an air-cooled motor carried forward.

Knox commercials, though a big family, are represented only by the three-ton four-cylinder truck, the engine of which is carried forward under the driver's seat, leaving a body space twelve feet long by sixty-eight inches in width. Wheelbase of this vehicle is 111 inches, tread being 60 by 62 inches, single solid tires being carried on the front wheels and dual solids, 36 by 4 inches, on the rear wheels.

Although the new E. R. Thomas Company's town vehicle occupies a place in the pleasure section, it is also entitled to representation in the commercial class as a taximeter cab, it being the intention of the company not only to equip the chassis with elegant town bodies for private city use, but to place a number of simpler landaulet bodies on the same chassis for taximeter service. The chassis, which is an entirely new production, having nothing in common with the touring models of the firm, has been designed with a view to compactness and simplicity and easy handling in traffic. The power plant, a model of compactness, consists of four cylinders in a single casting, the exhaust manifold being an integral part of the casting, provision being made for carrying off the heat by external flanges as well as a water jacket surrounding all valves. To further decrease the size of the engine the crankshaft is mounted only on two end bear-

THE ATTRACTIVE FRANKLIN CAB WITH AIR-COOLED MOTOR.

ONE OF THE FINE FREIGHT CARRIERS IN THE BASEMENT.

ings, the customary center bearing being abolished. Another distinguishing feature of the engine is thermo-syphon water circulation and the entire absence of piping, the only water connections being from the head and base of the radiator to the jacket surrounding the cylinders and valves.

Selective transmission has been employed, with the entire gear set combined in the differential housing on the rear axle. A double universal joint is provided on the propeller shaft, and connection to the power plant by a cone clutch is made through a special pivoting suspension, claimed to be an original feature.

Rear suspension of the Thomas cab is by full elliptic springs of a special design, attached to the side frame by means of projecting hangers; together with the low center of gravity, these appear likely to give very easy suspension and comfortable riding under rough road conditions. Control has been simplified to the operation of a clutch and brake pedal and a foot accelerator. The sparking point being fixed—a high-tension Bosch magneto is employed—no spark lever is needed on the steering wheel; the throttle control by means of lever has also been discarded, leaving the steering wheel absolutely free of all controlling arrangements. Gear changing by means of selective type is reduced to its simplest form; three speeds forward and reverse are provided, provision being made against accidental slipping in of the reverse by a stop on the sector to overcome which the driver must press on the head of the lever. To keep out dust as far as possible the gate sector has been almost entirely inclosed. The chassis to be used for taximeter service are fitted with a Popp taximeter operated by flexible cable.

In the electric section the General Vehicle Company provides the largest display with a couple of heavy trucks having separate

A GENERAL ELECTRIC CAR THAT WILL CARRY FRESH MEAT.

motors and side-chain drive, and one light delivery vehicle.

At the Baker stand the only exhibit is a police patrol van of regulation type so far as body is concerned, but driven by electric power. Pope-Waverly shows a series of light electric delivery vehicles. Studebaker makes a display of electrics, showing various models with bodies and one bare chassis. Single and double motor electrics are the feature of the Champion Wagon Company, two types being shown.

### THE SOCIETY OF AMERICAN GOOPS.

"The Society of American Goops" means that band of industrious press workers who endeavor to obtain as much free publicity as the wielders of the blue pencil will permit to filter into the news columns. During the annual shows, the "Goops" always get together, and to-night they are holding forth down in Houston street at "Little Hungary," where a gorge is taking place superior to the famous feasts of Lucullus—at least such is the case in the opinion of the "Goops," whose names are herewith given:

Toastmaster—R. H. Johnston, White Company.  
 Committees—Band, Alexander Schwalbach; songs and piano, R. H. Johnston; cars, menu and feed, E. Ralph Estep; invitations, Harry T. Clinton, Alexander Schwalbach, F. Edward Spooner, F. L. Farote; badges, press, Alexander Schwalbach, F. L. Farote.  
 Privates—C. W. Wurster, Stearns; A. L. Rich, Lozler; Charles R. Culver, Knox; J. A. Kingman, Locomobile; W. H. Workman, Packard; E. R. Estep, Packard; Charles Drysdale, Cadillac; F. Edward Spooner, Pierce; George M. Davis, Thomas; H. L. Humphreys, Welch; W. B. Walker, Franklin; H. M. Foote, Peerless; F. L. Faurote, Olds; C. W. Mears, Winton; R. H. Johnston, White; J. W. Drown, Corbin; J. F. Marstan, Pope-Toledo; John Coakley, Babcock; F. B. Hart, Rambler; C. G. Perceval, Cleveland; E. Leroy Pelletier, Ford; A. B. Tucker, Dragon; N. Lazarnick, Daguerre; Alexander Schwalbach, Darracq; Harry T. Clinton, A. L. A. M.; Arthur N. Jervis, Berliet; Duncan Curry, A. C. A. Show; Joseph E. G. Ryan, Chicago Auto Show; L. M. Bradley, A. M. C. M. A.; Jack Hisecock, Philadelphia Show; Howard Reynolds, Boston Show; J. W. Gogarn, Reo.

### CHICAGO MOTOR CLUB'S 630-MILE CONTEST.

CHICAGO, Nov. 5.—Plans have been completed by the contest committee of the Chicago Motor Club for the 630-mile sealed bonnet reliability contest to be held the week the automobile show opens at the Coliseum. The dates set are November 26, 27 and 28, and the show will open two days later. The first day the cars will be sent to South Bend, Ind., and return, a distance of 230 miles. The second day to Rockford, Ill., and back, 200 miles, and on the third day to Ottawa, Ill., and back, another double century.

The trophy of the endurance contest, designed by Henry Thiede and modeled by H. G. Donar, of Chicago, is cast in bronze and mounted on an ebony base. Its height, including the base, is 42 inches. It is intended to make 150 reproductions of the trophy to be used as part of the decorations of the Chicago show, each one being mounted on a decorated column trimmed with red plush, with white and gold effects. The valuable and artistic trophy has been offered by S. A. Miles, general manager of the National Association of Automobile Manufacturers, which conducts the big show in the Coliseum.

ARTISTIC TROPHY FOR THE CHICAGO ENDURANCE RUN.

# Concerns That Took Garden Space Only

WHAT would an automobile show be without its wealth of accessory exhibits which lend so much of life and variety to every event of the kind? And usually the accessory maker and dealer is to be found wherever there is such a thing as an automobile show, even though two happen to follow each other in such close succession as is the case with the recent affair in the Grand Central Palace and this week's show in the Garden. There are some exceptions to this, however, in the shape of makers who are confining their efforts to the licensed show in the Garden, among those who are making a display in the latter alone, being the following:

**Avery Portable Lighting Company.**—"Autogas" tanks, made by this concern, at its factories in Milwaukee, Wis., are shown in two sizes, the smaller measuring 6 by 22 inches, containing 50 feet of gas ready for use, and weighing 30 pounds, while the larger cylinder measures 7 1/4 x 22 inches, contains 85 cubic feet of gas, and weighs ten pounds more. These tanks were invented by P. C. Avery in Chicago early in 1903, and were first known as the "Averylite tank." The tanks are made by pressing a disk of steel into the required shape, thus making the cylinder seamless, except at one end, which is accurately fitted and brazed in. Each tank is tested to a pressure of 600 pounds and has a tensile strength of 1,500 pounds to the square inch, though the normal gas pressure never exceeds 300 pounds. Should the tank be placed in a hot fire, a special safety plug with which it is equipped will break at 500 pounds pressure.

**Bethlehem Steel Company.**—Pressed steel frames of standard patterns, dropped-forged axles, crankshafts, steering knuckles, and a number of other automobile parts in special steels, rolled particularly for this purpose, go to make up this firm's exhibit. They also show samples of a line of high-speed tool-steel, specially adapted to working automobile steels. As they have one of the largest drop-forging plants in the country, the range of parts which they are equipped to make covers everything for which a drop-forging may be employed on a car.

**Brennan Manufacturing Company.**—Where motors are concerned, this firm is in an excellent position to take care of the demand for both air and water-cooled patterns in the four-cycle type. They show examples of both in the four-cylinder vertical type, but also make the horizontal opposed twin-cylinder type, embodying many special features of their own design, as well as six-cylinder vertical motors, which are extremely compact power units. They are representative of the highest current standards

of motor design, and particular attention has been paid to attaining the maximum of simplicity.

**Columbia Lubricants Company.**—All oils look alike to the average visitor to automobile shows and, as a general rule, exhibits of lubricating oil are not the most attractive things in the world to the man in the street. But it is quite different with brands such as the "Monogram" shown by this concern especially for automobile use, and to which they have devoted their attention for several years past. In the name "Monogram" many an autoist recognizes a familiar friend.

**Dow Tire Company.**—Although it is less than a year ago since the Dow non-deflation tube was presented to the automobile world, the record it has made in the meantime has been such as to attract widespread attention from autoists generally. The exhibit of this concern is consequently of more than passing interest in that the performance of driving nails and other puncture-producing devices into a pneumatic tire without the latter losing its inflation, is somewhat puzzling at first sight. The Dow inner tubes are made of two layers of a special material around the greater part of the circumference. Between these two layers is placed a special compound which has the property of automatically healing punctures in the tube.

**Cook's Standard Tool Company.**—Every autoist knows the Standard jacks, for they were one of the first for automobile use to be placed on the market. They are of the single-acting type in which the car is lifted or lowered only on the downward stroke, the upward stroke being free. They are shown in a number of sizes, capable of lifting the heaviest cars made.

**Dietz Company, R. E.**—It is evident that this concern has had its ear to the ground during the past year, as one of the things to be found in its exhibit consists of a line of lamps which are shown in a handsome black enamel finish, designed to correspond with the polish of the rest of the body, and which will not require any attention in the way of cleaning, which is the greatest drawback of the polished brass lamps. They also show a complete line of searchlights in different sizes, together with the Dietz generators. The latest productions in square side lamps for both electricity and oil are also a feature of their showing.

**Duff Manufacturing Company.**—"The jack that Duff builds," in other words the Barrett automobile jack, is the subject of this exhibit. They are shown in both single and double-acting types and embody an improved lowering device. They are compactly proportioned, very substantially made, and very simple to operate.

**Empire State Tire Company.**—Numerous claims of superiority are made by the makers of these tires over other types, for the reason that the tread of the Empire is extensible, and consequently, when inflated has a much greater wearing surface than is usually the case. The successive discontinuation of the layers of fabric at the hinge, and the substitution of layers of rubber, renders the universal breaking at this point practically impossible and prevents blowouts, except as a result of direct puncture. This firm also shows the Greenwald non-skid tread and a puncture-proof armor known as the "internal protector."

**Edouard Dubied & Company.**—This concern is represented in this country by Ch. Dien, who shows the "Edco" spark plugs made by them. The latter have several advantages in construction, the absence of a joint between the insulator and body of the plug making it perfectly gas-tight, while the insulator of steatite is milled directly into the metallic body of the plug, thus giving hermetical sealing. Ch. Dien also shows a line of valves, lugs, screws, nuts, non-skid rivets and chrome leather.

**Hardy Company, R. E.**—"Sta-Rite" specialties form the subject of this firm's exhibit and include such things as ignition plugs, spark coils, and automobile accessories. The "Sta-Rite" plugs have been adopted as a standard part of the equipment of a very large number of American cars, and are probably made in a greater number of different styles, types and sizes than any other line of plug on the market. In fact, there are six distinct styles and 47 sizes, the patent rights and the exclusive sale of these plugs being owned by this company. This firm also makes a line of mica insulated plugs, as well as high-tension spark coils.

**Hoffecker Company.**—Hoffecker speed indicators and mile registers form the subject of this firm's exhibit, and several of them are shown in operation. In some instances this is done with a glass enclosing case substituted for the usual metal case, so that the spectator may note the extreme simplicity of the apparatus as well as the manner in which it works. Just what the interior of the usual speed indicating apparatus might consist of has long been a puzzle to the average person, so that this method of displaying the instrument attracts a great deal of attention.

**Indestructible Steel Wheel Company.**—Automobile wheels of a totally different type that well merit the name of "indestructible," are shown by this firm. They are of pressed steel put together by riveting, the whole being especially designed and offering many advantages for automobile use. They are made in three gauges of metal, weighing from 11 1/2 to 18 pounds up per wheel, making them applicable to all weights and sizes of cars, and having a carrying capacity of 15,000 to 50,000 pounds, for pleasure or commercial vehicle use. The pleasure model is made particularly light by means of perforations between the spokes. The fact that these wheels are employed on the car used by the circus performers in "Looping the Gap" speaks for itself.

**Janney-Steinmetz & Company.**—Among the numerous specialties shown by this firm, doubtless the one which attracts most attention is the Hill lock valve, otherwise known as the "automobile hitching post." This is a Yale lock cut-off for the gas-line pipe, equally adaptable to either gravity or pressure feed, and which effectually prevents a car from being stolen. They also show their line of cold-drawn seamless steel tanks.

**Kilgore Manufacturing Company.**—Here the autoist is invited to "ride on air," as the Kilgore shock eliminator is the only one of the pneumatic type on the market, acting as it does on the same principle as the car's tires. The Kilgore eliminator works on the principle of actually absorbing the shock in compressing air, this being clearly illustrated at the exhibit.

**Pittsfield Spark Coil Company.**—One of the latest things shown by this concern is a new high and low-tension switch, made for use in connection with their own type of high-tension magneto and also as part of a four-unit coil, such as is generally used in the standard dual system of ignition. The Pittsfield magneto, which is of the high-tension with non-vibrating coil type, has been greatly improved since its first appearance last

year, and is shown in operation in connection with the Jewel plugs, made by this firm, as well as their new switches. The latter are of extremely neat design, all external parts being of polished hard rubber. They also show a complete line of coils for every form of service, including motorcycle, boat, stationary and dashboard use, as well as the Pittsfield timer, which is made in all sizes from one to eight cylinders.

**Precision Appliance Company.**—No better means could be devised to show the accuracy, reliability, and smoothness in action of "The Shooting Oiler" than the makers of the Hill Precision oilers have adopted at their stand. This represents the dash of a car with a glass footboard, beneath which is a small tank. The different leads from an oiler, which is being run by a small electric motor forward of the dash, terminate just under this glass, so that the spectator is given an interesting object lesson in the regularity of mechanical force-feed lubrication. By looking on the other side of the dash there may be seen the mechanism required to accomplish this object.

**Rushmore Dynamo Works.**—The chief thing of interest to the visitor at the exhibit of this concern is a 30-inch lens for one of the huge battleship projectors used in the U. S. Navy. This is shown in the rough and gives an excellent idea of the vast amount of work that must be required before it emerges in the finished state, as surmounting it are shown two finished mirror lenses of smaller size. This concern also exhibits a complete line of their automobile searchlights with Rushmore generators. Complying with the demand that is beginning to make itself felt, some of these are displayed in an attractive dark finish.

**Smith & Son, S., Ltd.**—Among the novelties shown by the makers of "Perfect speed indicator" is one specially designed for use on limousines. On the dash this shows a speed indicating dial, a clock face, and an electric annunciator with the usual signal. On the interior of the limousine body there is a duplicate of the speed indicating dial, and the button plate for operating the annunciator. They have also taken the agency for the "Crack" electric horn attachment, which may be fitted to any horn, so that the latter can be blown at will either by an electric button on the steering wheel or by the usual bulb.

**Springfield Metal Body Company.**—This firm makes a specialty of manufacturing aluminum and steel bodies, hoods and fenders for automobile use. Samples of completely equipped open and closed bodies are shown at their stand and form striking illustrations of the efficiency of this type of construction, on which the builders hold a number of patents. Their line includes every standard form of body, such as the popular straight line, five and seven-passenger tonneau, curved line bodies of their own design, runabouts, surrey types, and various inclosed bodies.

**Stackpole Battery Company.**—This firm manufactures a line of dry cells specially designed for automobile and motor boat use and of which they show a complete assortment in varying sizes at their exhibit. The brands under which the cells are made for this service are the "Autocrat," "Wizard" and "Radium."

**Uncas Specialty Company.**—The Leavitt secondary distributors and spark timers, which are shown in operation by this concern, always prove a never-failing source of attraction to the autoist who is interested in improving the ignition of his car, as well as of the manufacturer investigating the merits of new specialties in the ignition field. The primary timers are made in a range of sizes from single to six-cylinder motors and are of the ball-contact type, though this firm also shows a line of wipe-contact timers of the roller type, known as "The Leavitt timer, La-coste pattern," beside which they show other Leavitt specialties.

**Vacuum Oil Company.**—Vacuum Mobiloils are too well known to the average autoist to require any particular introduction, although the exhibit of this concern in the basement has been made unusually attractive considering the nature of the article shown. A stack of varnished oak barrels reaching half way to the ceiling, each one bearing a different brand, gives some idea of the numerous grades of lubricating oil refined.

### WHAT THE ELECTRICS REVEAL.

There is a quiet air of refined dignity about the restaurant annex at the Garden that is totally lacking, either in the main arena itself or any of the other overflow exhibits, for this year it is wholly given over to the exhibition of electric vehicles, and it may be added—there was not enough space to go 'round, so that some of them were compelled to exhibit in the basement. Everything is so clean and neat about an electric—in fact, they are the embodiment of luxury and comfort, so that such things as dirty oil or gasoline seem totally foreign to them. This does not seem to be the case with some of the cars staged by the General Vehicle Company, as they bear such a close resemblance to the standard types of gasoline cars that they are frequently mistaken for them. This concern exhibits a line that marks quite a departure in the way of electric vehicle design, in that a great deal of the experience gained in the gasoline car field has been taken advantage of by the electrical engineer. Thus the pressed steel frame, the long semi-elliptic suspension and the standard form of wheel steer have been utilized, while an extremely natural looking bonnet has been impressed into service to house the battery. Further, the somber colors of the coach builder have given way to the more attractive finishes familiar on gasoline cars, and the bodies are patterned after the type used on the latter, so that the resemblance is complete. But the greatest improvement has been made in the power plant and drive, now much more efficient.

The Baker runabout is another production that appears to be out of its element in the midst of a number of electric cars, as

since its first appearance last year, this electric roadster has been considerably improved and is difficult to distinguish from the most up-to-date type of gasoline car. This concern also exhibits a complete chassis illustrating the simplicity of the mechanism of an electric as exemplified by their special design and construction, together with several of their leading types of cars, such as a coupé, though the most striking car in the Baker exhibit is a hansom cab with the driver's seat forward. The "Babcock Idea" in electrics is illustrated by several of the cars of this well-known make, supplemented by a collection of attractive literature on the subject, which tells of the things the Babcock electrics have achieved in their long and successful career. The line of Columbus electrics is one of the most complete to be seen, and in addition to several types built by this concern, it also includes a

complete chassis. Pope-Waverley is synonymous with electrics and one of the special types of rear axle driving units with its hering-bone gears as employed on these cars shows how they differ in design from other electrics and the reasons for their superiority. They also exhibit several of their standard types of complete cars. There is a most complete showing of the pioneer Columbia electrics, particularly in the heavier types such as broughams, and the length of time this make has been on the market is a recommendation that speaks for itself. The R. & L. electrics, made by the Rauch & Lang Carriage Company, Cleveland, O., complete the exhibits in this section and they are particularly worthy of attention. The Detroit electrics made by the Anderson Carriage Company, Detroit, Mich., are shown in the basement.

### Gossip of the Show

**Col. George Pope, Chairman Exhibition Committee:** "No exhibition equal to it has ever been held before in this country. It marks an epoch in the construction of automobiles, and the man who cannot satisfy his automobile wants, be they large or small, in the present show, is certainly a difficult one to please."

\* \* \* \*

**W. E. Metzger, of Executive Committee:** "We are thoroughly pleased with the show; agents are here, business is being done, and genuine interest is shown in the exhibits. I believe that there are more people here during the day than at any previous show, though the gate receipts have not been announced yet. Personally the show is held rather too early, the October date having a tendency to cut down Autumn sales."

\* \* \* \*

**Charles Clifton, President A. L. A. M.:** "Certainly the show is an excellent one, the exhibits being superior to anything shown before in this country. There is a sense of proportion about the hall, an excellent showing of the exhibits without anything being hidden by decoration, that is thoroughly pleasing. Having just arrived from a city where the dollar is not as mighty as in New York, but where we still pay out in hard cash, I am not able to judge more closely the results of the show. Naturally

the financial disturbances will affect us, for automobiles cannot be produced automatically whatever the conditions and stored up until there is a demand for them; but the tightness is not likely to be more than a condition that is merely temporary."

\* \* \* \*

Football and automobiles have few things in common, but the advent of the many sixes has been responsible for the memorizing of cabalistic trains of figures on the part of the numerous salesmen, and not a few of the visitors have been surprised to overhear one of these attentive and earnest, dinner-coated, walking encyclopediæ of automobile lore at the Peerless stand say in all seriousness to an interested onlooker, "1-3-2-6-4-5"—and his hearer seemed to be "on." He had his little book by heart, did this "explainer," but at most of the other stands where sixes were a feature the answer was usually: "I'll give it to you in a moment; I have it in my note book." "It" was the order of firing of the cylinder of the sixes, and the reason for the unusual interest displayed in this fact was that each maker seemed to have worked out a different combination. In the Oldsmobile this is 1-4-2-5-3-6, and in the Winton 1-5-3-6-2-4, and different combinations are to be found on the other sixes, the only thing they have in common being the use of the forward cylinder as the starter. Among the visitors there is a tendency to catch on quickly to the technical details.

\* \* \* \*

The fair sex displays much keener interest in the exhibits at the Garden than has ever been shown before. The interest, too, is not merely in the upholstery, mirrors, and toilet requisites of the various handsome limousines, but in the mechanical construction of engines and transmission. At one stand a fair visitor was deeply interested in the starting handle, and, with a skill that revealed more than a passing acquaintance with the gentle art of cranking, seized the lever of a well-known make and pointed out a structural arrangement which made it difficult for a lady to start up that particular car. Another fair visitor discoursed on the make-up of a gear box in a manner that would have been a credit to a mechanic. Women at the steering wheel, testing the disposition of the pedals and levers from their standpoint, were frequent.

\* \* \* \*

"What's that gasoline car doing in here with the electric?" is a question that is asked every time a newcomer to the Garden strolls in among the attractive collection of *de luxe* electric vehicles in the restaurant annex, and the surprised query is well-justified, for some of the new General Electric pleasure cars, with their bonnets of the conventional type concealing the batteries, their standard wheel steers, and, more than anything else, the usual bronze side levers, look like anything but electric cars. It is difficult at first sight for even the most experienced autoists to distinguish the difference, and this is made doubly so by the fact that many of the latest models of gasoline-driven cars have dashboards that are practically free from the encum-

brances of oilers, coils, and switches that formerly made them easy to recognize. When Alexander Churchward, the designer of the new General cars, drove one of them up to the Garden door, he was warned to take the gasoline out of it before taking it into the building.

\* \* \* \*

Probably there are few better authorities on the good points of six-cylinder construction than "Teddy" Dey, who has charge of the exhibit of the George N. Pierce Company, which shows a "big" and a "little" six. And his is the

STAGE COACH TYPE SHOWN IN POPE-TOLEDO EXHIBIT.

familiarity of personal experience, not theory, for he handled the first "Big Six" Pierce in the A. A. A. tour of a year ago, and went over the route of this year's tour twice in the same car—first as a pathfinder, and secondly in the tour itself, in which he made a perfect score, being instrumental in large measure in again winning the trophy for the Buffalo club.

\* \* \* \*

Real interest, and not mere idle curiosity, was a characteristic of the Garden display. This could be better judged

MECHANICIAN'S SEAT A FEATURE OF THE STEARNS.

by the crowds on the galleries than on the main floor, and, although it involved climbing a steep stairway, visitors were always plentiful "up aloft." If for no other reason, it was worth going up merely to note the many ingenious appliances designed by accessories exhibitors to attract the attention of passersby. Some of the "stunts" of the electrical men were hugely successful.

WHERE THE APPERSONS WERE ADVANTAGEOUSLY PLACED

It did not take long for feminine New York to spot the dainty Packard runabout built "for two and a man behind" as "just the loveliest, dearest little thing." With its delicate lavender finish set off by gold striping and pure white upholstery, it only seemed natural to dub it the "honeymoon car," which was done forthwith. It has been the cynosure of all feminine eyes ever since the show opened, and scarcely a girl leaves the Packard stand to pass on to another without a backward look of longing: "Isn't it just too cute!"

\* \* \* \*

Miss Hebe White moved from the Palace to the Garden without soiling the spotless raiment that adorned her at the former place, and it only goes to show how clean a nice girl can keep herself, even if there is a whole lot of "nasty oil" around, for Miss Hebe holds forth at the stand of the N. Y. & N. J. Lubricant Company, and she's as good a "mixer" as the non-fluid oils, which she takes pleasure in telling visitors all about, and she doesn't have to look sharp when showing how smoothly the non-fluid lubricant sticks to business in the Matheson gear-box, because it stays where it is put.

\* \* \* \*

Driving nails into an inflated tire, and then running it under considerable pressure corresponding to the load of a car on the rear wheels, at a rate equivalent to the usual travel of a car, never fails to draw a keenly interested group of spectators about the stand of the Dow Tire Company, who have designed an elaborate apparatus to simulate the conditions under which a pneumatic tire runs when on a car. It certainly puzzles the average man to figure out why the air does not follow the good-sized nail when it is drawn out of the tire, but it is a matter that is easily explained.

SOME OF THE WELL-KNOWN FIGURES OF THE INDUSTRY SEEN ABOUT THE GARDEN.

## THOMAS HENDERSON ELECTED N. A. A. M. PRESIDENT

AT the annual meeting of the National Association of Automobile Manufacturers, Inc., held at the Hotel Victoria, Wednesday morning, Thomas Henderson was elected to the presidency, succeeding Albert L. Pope, who presented a very complete and exhaustive report of the work of the association during the past year. Hereafter the initiation fee for membership will be \$500 instead of \$25.

These members of the executive committee were re-elected to serve for three-year terms: S. T. Davis, Jr., L. H. Kittridge, W. E. Metzger, Charles Clifton, and S. D. Waldon.

At the meeting of the executive committee, which followed the annual meeting, these officers were elected: President, Thomas Henderson; first vice-president, S. D. Waldon; second vice-president, W. E. Metzger; third vice-president, L. H. Kittridge; secretary, C. C. Hildebrand; treasurer, W. R. Innis.

Responding to the request of the American Automobile Association for the appointment of a member for a conference committee composed of delegates from various national automobile bodies, the president was instructed to make such an appointment. The suggestions relative to racing on circular tracks, recently adopted by the conference held under the auspices of the A. A. A., were referred to the N. A. A. M. contest committee.

In the course of his report, retiring President Pope said:

It has been the good fortune of all my predecessors in office to be able, in opening their annual report, to congratulate you and the entire industry upon the favorable conditions under which the automobile business has been conducted. At our last annual meeting the retiring president noted that the members of this association had been reasonably conservative in the number of cars produced, and expressed the opinion that so long as this conservatism went hand in hand with quality the automobile industry would be conducted on a safe and sound basis. The wisdom of the advice implied by his remark has been proven by recent events.

Not because of over production; not because there has been any falling off in quality; not because the country is less prosperous or the purchasing power of the people is exhausted, but because of abnormal conditions for which no manufacturer can be blamed, which no manufacturer could accurately foretell, and against the effects of which no manufacturer can consider himself absolutely proof, the time has come when I consider it my duty to emphasize the remarks of your last president, and to say that it is now necessary, and will, in all probability, continue necessary all through the season of 1908 and possibly well into the season of 1909, to exercise the utmost caution.

Even the ablest of our financiers is unable to accurately forecast the conditions that will prevail during the next few months. We know that the prosperity of the country is as great as ever, we know that the people of the country individually have more wealth than ever before, we know that no real reason exists for supposing that these splendid conditions will undergo an early change. But

wealth is not money, and at present we have not sufficient money in circulation to represent the wealth and facilitate its transfer.

Perhaps so far as the automobile industry is concerned this condition is not in all respects deplorable. Encouraged by unfounded stories of fabulous profits there have come into the automobile industry so many manufacturers, all seeking to do business on so large a scale, that the production might easily exceed the demand. It is an extremely fortunate fact that most of the older, better, and more conservative manufacturers have exercised great caution in production. But as to the less conservative element, it is not unlikely that had nothing occurred to cause them to pause; either of their own volition or perforce, the production would have been excessive. We all realize that this would have meant failures, demoralization of prices among the less important manufacturers, and an uncomfortable time for the entire industry until these troubles had, in the ordinary course of business, been cleared away.

The automobile industry can, therefore, learn from the existing conditions a splendid lesson. It can learn that only in times of prosperity can the country absorb the number of cars which the manufacturers are now able to make; it can learn that the prevailing conditions will result in a closer scrutiny of quality than has heretofore existed; it can learn that only those with abundant capital can safely expect to manufacture cars in large numbers, and then only provided they possess the necessary plant and selling organizations to enable them to produce and market their goods more economically than they have been doing; in other words, that it will be necessary, not perhaps to lower prices, but to provide better cars than ever before for the money asked. They can learn that it is far better to make 100 cars at a profit than 200 without profit or loss or 300 resulting in failure.

It has been the policy of the Executive Committee of the National Association to admit to membership only those concerns on which it can count for conservative action in times like the present, and for excellence of production under all circumstances. Membership in the National Association does, and I hope always will, stand as a guarantee of these requirements.

This does not mean, however, that there are no manufacturers outside of the association possessed of the qualifications above set forth. There is another reason, and it is found in the fact that there is in the treasury of the association a large sum of money which belongs to, and exclusively to, the present membership. The executive committee has regarded itself, as it unquestionably is, as responsible to the members for the proper care of these finances. The members of the executive committee do not feel that as caretakers of the fund they are warranted in decreasing the interest therein of any member by the admission of some new member, who would thereupon become entitled to a full interest in the fund, unless that member brings to the association some strength and a sufficient return for the interest which, by admission, he would obtain.

The present initiation fee is \$25, upon the payment of which sum a new member would become entitled to, approximately, a one-fiftieth interest in a fund of approximately \$40,000, which will, in all probability, be shortly increased by a substantial profit upon the Chicago show.

# A 1,000 Miles of New England

THROUGH CRAWFORD NOTCH.

*By A. F. Westgard*

THE ROAD NEAR LENOX, MASS.

**A**FTER sifting many plans for two weeks' vacation this summer, we finally decided upon a tour which would offer fair roads, great diversity of scenery, and a good hotel at the end of a day's journey. Being the proud owners of a model R Ford runabout, we received a great many admonitions from well-meaning friends not to undertake such a long tour as we had mapped out, owing to the mountainous character of the country and the length of the trip, a thousand miles or so.

However, we went ahead with full confidence. We fitted out with extra shoes, inner tubes, and spare parts, which, with our baggage, altogether weighed some two hundred pounds. Suit cases were enclosed in rubber sheeting and disposed of on the running boards and on the top. Beside, we carried a refrigerator basket for lunches, as we expected to eat our noon-day meal "a la picnic."

## On the First Day, 92 Miles.

Our first day's trip carried us from New York along the Boston Post road through Greenwich and Bridgeport to Stratford. We found that the road was being repaired at several places, necessitating a couple of detours. The traffic was heavy on this part of the trip and the scenery not particularly attractive, as the road for the greater distance lies so far back from Long Island Sound.

From Stratford we turned inland, following the Housatonic river to Shelton. This was a good gravel road and offered many scenic beauty spots. Crossing the river at Shelton, we followed the valley of the Naugatuck river north. The road is somewhat marred by being paralleled by a double track trolley line, but many charming vistas of the river were enjoyed before reaching Waterbury. Here we put up at The Elton. It was more than a pleasant surprise to find a hotel of such uniform excellence in a manufacturing town of the size of Waterbury. We were made thoroughly comfortable and Manager Judd took great interest in advising us of the condition of the roads to be encountered in our next day's journey. The distance covered the first day was 92 miles, negotiated without a hitch.

## Into the Berkshires on the Second Day.

The next day continued us up the Naugatuck valley through Thomaston and Torrington to Winsted, over fair dirt roads with more fine scenery. From Winsted we turned west to Norfolk; on these few miles we encountered the first of any heavy going we had met with so far. It was up grade and sandy, but our little car did it splendidly. Beyond we found fine roads and a great deal of macadam through Great Barrington and Stockbridge to Lenox, Mass. We were now in the far-famed Berkshire Hills. Putting up at The Aspinwall, located on top of a considerable knoll, we enjoyed all the comforts of another first-class hotel, with beautiful views in all directions. A commodious garage is located within the hotel grounds and the little car got a well-earned grooming that night. The distance covered the second day was 74 miles.

Starting out the third day we skimmed along a road to Pittsfield, whence our route led via Lanesboro and New Ashford into the very heart of the Berkshires, with majestic Greylock towering on our right. The views were particularly fine, the road dirt but good. Arriving at the old town of Williamstown we were informed that the speed limits were being rigidly enforced and that we had better "keep crawling." We "crawled" past the venerable buildings of Williams College and struck out up the Hoosic valley to Pownal, Vt. Here we did our first serious stunt of hill climbing. The road leads up along the side of a hill and its steepness, narrowness, and number of waterbars would have long remained in our memory were it not all forgotten and forgiven on account of the enchanting views of the beautiful valley below.

Continuing north over more level country, we passed through Shaftsbury to Bennington and took a snapshot of the famous Battle Monument. Shortly beyond Bennington we encountered another stiff climb, beyond which the country was rolling and the road fine the rest of the way to Manchester. On entering this town we passed the splendid golf links of the Ekwanok Country Club, said to be one of the finest in America. The town is situated in a beautiful valley at the foot of Mount Equinox, which rises thousands of feet above it. We were made comfortable at The Equinox House, one of the old hostleries of the New England States. We covered 64 1-2 miles during the day.

## Granite State on the Fourth Day.

Upon mentioning that our next day's route led over Peru Mountain on the other side of the valley, we were told all sorts of horrible tales of its steepness and its many "thank-you-marms," but by this time we felt that our "pocket edition" could overcome any difficulty of that nature, so we started out full of confidence. Three miles from town, just beyond the village of Manchester depot, we began to strike the grades, at first easy, then more steep. Just at the foot of the mountain itself we were pleasantly surprised to find a toll gate, as this led us to think that the half-dollar tax must indicate that the road ahead certainly had had some attention. This, however, proved not to be the case. It seems to be entirely "a la nature." We had three and a half miles of steady climb, not so very steep after all, but owing to hundreds of waterbars, one every thirty to forty feet, we were compelled to take the entire ascent on the slow speed. This naturally tended to heat our small high-speed engine. However, we backed down into one of the water-breaks four or five times and got cool water from the brook alongside the road and thus had no difficulty in gaining the summit. We were the first who had ever taken a low-powered runabout over this mountain, and, of course, we were duly proud.

The road now led down long grades through Peru to North Derry, beyond which town we had another stiffish climb, then down more grades via Simonsville, through Chester to Spring-

OLD MASONIC BUILDING.

An ancient landmark at Woodbury, Conn., about 200 years old.

view to the westward. We covered 74 1-2 miles this day.

The next day it rained in the forenoon, and we spent the afternoon making a circuit of the lake with Manager Marvin, of the hotel, who pointed out the beauty spots of enchanting Lake Sunapee.

#### In the White Mountains on the Fifth Day.

Our fifth day on the road carried us over uniformly good dirt roads via Danbury to Bristol in the Pemigawasset Valley. Here we struck out north, skirting the east shore of beautiful New Found Lake to Plymouth and encountered some four miles of heavy sand near West Campton. We were now entering into the White Mountains region, as evidenced by the towering hills around us. However, the road up the valley to Flume House was not at all hilly. We took a good view of the profile of "Indian Head," just beyond the hotel. The only serious climb is in the Franconia Notch, about a mile beyond Flume House. Upon reaching within a hundred feet of the very top of the grade we encountered a short steep pitch which brought the gasoline below the level of the carbureter and we were "stuck." How we regretted not having procured a little extra "gas" at Bristol or Plymouth! However, regrets were vain—we sat down and waited, and it was fast getting dark, too. In the course of time—it seemed such a long time to us—a team came up the hill. The driver generously offered to go to the Profile House, three and a half miles distant, for some gasoline. Needless to say his offer was accepted; it might also be added that the boasted price of one dollar a gallon for gasoline frequently paid by tourists in Europe "looked like thirty cents" when compared with the cost of the small quantity we needed. After a couple of hours' tedious wait there in the woods we were once more under way. We had intended to keep on to Bretton Woods, but decided to spend the night at the Profile House in order to view the famous "Old Man of the Mountain" by daylight.

Next morning we had a good look at this freak of nature, a perfect profile of a face appearing at the very edge of a precipitous cliff only a few minutes' walk from the hotel. We continued over a sandy road to the Profile Golf Links, whence a new fine gravel road led direct to Twin Mountain House. From there the road, now more sandy, with numerous railroad grade crossings, followed the Ammonoosuc river direct past Fabyans to Lretton Woods, in the very heart of the mountains. We had traveled ninety and a half miles since leaving Sunapee Lake. Bretton Woods is a sort of kettle surrounded by towering mountains, Mt. Washington, the hoary giant, overtopping the rest. The Mount Washington Hotel, where we stopped, is located on a knoll in the very center of the kettle, the Mount Pleasant House, under the same management (Anderson & Price), is at its western edge, and half way between the two hostleries

are the garages, with room for seventy-five cars, and The Bretton Arms, which is run as a hotel for chauffeurs. Beautiful golf links extend to the south from the hotels. A couple of days were spent in thorough enjoyment of this magnificent region and its splendid hotels. The little car, too, got a cleaning; but let me say right here that, aside from carbureter adjustment made necessary owing to the difference in altitudes, it needed no attention.

#### The Sixth Stage Ends in Maine.

With regrets we left Bretton Woods and set out on the sixth stage of our journey, heading for Crawford Notch, in sight some three miles distant. We passed Crawford House and, entering into the "Gate of the Notch," the road wound down steep grades through the woods; the surface was, however, excellent for motoring. Passing between Mount Webster on the left and Mount Willey on the right, we finally emerged into more level country and followed the Saco river through Bartlett, past Glen Station and through Intervale and North Conway, splendidly located summer resorts. Just beyond North Conway we took a left fork of the road and went via East Conway, which offered a better road than the more used route via Center Conway, to Fryeburg, Me. The road was good dirt surface to Bridgton and Naples. Some fine bits of scenery along the numerous ponds and lakes on these Maine roads.

The route from Naples had a few miles of sand and two short but steep hills before we arrived at Poland Spring, Me., seventy-seven and a half miles from Bretton Woods. Coming as we did from the rugged nature of the mountains the peaceful and restful nature around the justly famous Poland Spring House acted like balm to a feverish patient. This hotel has magnificent golf links and beautiful views, and pure water and air. An ample garage is connected with the hotel. We were so contented that we tarried a day longer than intended.

#### Newcastle, N. H., on Seventh Day's Ride.

The seventh installment of our trip led us south over fine gravel roads to Portland. We skirted the beautiful harbor with its many islands and crossing the Fore river started with many misgivings on a stage of the route which has always enjoyed

ROUTE OF THE 1,000-MILE NEW ENGLAND TOUR.

ONE OF THE MANY GRAND VIEWS IN THE WHITE MOUNTAINS.—IN FOREGROUND, FRANCONIA INN AT SUGAR HILL.]

an evil reputation on account of its alleged sandy condition. Though we encountered some sand in two or three short stretches we found the road not at all so bad as anticipated. From Biddeford to Kennebunk the road traversed a woods, and though a little bumpy, it was quite fair going. It would seem, however, that in wet weather this particular stretch might be pretty trying. Beyond Kennebunk the road was good. We went by York Beach and York Village, crossing the Piscataqua river into Portsmouth. We did not stop in the city, but kept right on for about three miles beyond to The Wentworth Hotel at Newcastle, 81 miles from the morning start. This place was made famous as the abode of Japanese and Russian peace commissioners and is justly entitled to its reputation as a delightful hotel. It has fine views of the ocean and Portsmouth harbor with its navy yard. It also has golf links and a good garage.

#### Boston at the Conclusion of Eighth Stage.

Our next day's trip being short, we started late in the forenoon and passed calm and peaceful Rye Beach and Boar's Head to Hampton. The trolley line kept us company all the way to Newburyport, Mass. As we for the first time had failed to load our lunch basket we were quite ready for lunch and were directed to Wolfe's Tavern, the only hotel in the town. Here we met with our first disappointment on the tour.

We had had good macadam roads since leaving Newcastle and these continued all the rest of the day, through Beverly and Salem into Lynn. From Lynn we went over the new Revere Beach boulevard, and it was certainly fine, curving from it directly into Fellsway, over which splendid parkway we rolled smoothly through Somerville into Cambridge. We had a little difficulty in finding our way through the cobblestone paved streets to Massachusetts avenue, which leads direct to bridge over Charles river. Three blocks beyond bridge we turned into Commonwealth avenue, Boston, 68 1-2 miles from Newcastle.

#### Next on to Springfield, Mass.

Next day's trip was a pleasure indeed. Splendid macadam brought us out Commonwealth avenue, through Weston and Marlboro to Worcester. Thence through Leicester, where one ascends the only hill worth mentioning in the run to Springfield. Between West Warren and Palmer are about seven miles of bad dirt road, narrow, sandy and rutty. One cannot help wonder how a State with such a large percentage of fine improved roads can allow such a condition to exist on its most used trans-state highway. We spent the night in Springfield, after covering a distance of 96 miles that day.

The tenth stage of our tour brought us down the east side of the Connecticut river, by acres of green tobacco fields, and across the bridge into Hartford. Thence via New Britain and Bristol to Plymouth, good going all the way. The distance of about one mile between Plymouth and Thomaston is down a hill so steep that even in spite of the confidence inspired in us by the past hill-climbing performances of our little Ford we were glad that

the grade was down instead of up. From Thomaston the nine miles to Waterbury was the only road which we covered twice in our long journey. We made the sixty-one and a half miles to Waterbury in fine shape, the little engine still running as smooth as oil. We were glad to once more be under the hospitable roof of The Elton. Owing to the general excellence of the roads there is no reason why an average touring car could not comfortably cover the entire distance from Boston to Waterbury in one day. The 157 miles should prove as easy as many a trip of half the distance.

The eleventh and last day of our travels carried us through Woodbury, where we inspected the Masonic Building, over two hundred years old, a venerable and interesting piece of architecture. Thence through a scenic beauty spot along the Housatonic river to Danbury. Eight miles beyond, at Sodom Reservoir, the route turns up a bad dirt hill, but two miles further at the Westchester County line begins a stretch of some 58 miles of fine macadam, which made the rest of the trip via Bedford and White Plains a joy all the way back into New York, ninety-seven and a half miles for the day.

#### WHERE A NEW LAW IS NEEDED.

CHATTANOOGA, TENN., Nov. 2.—Catoosa county, Ga., has an automobile law which undoubtedly holds the record for severity. This legal enactment provides for a speed limit of ten miles an hour throughout the county, and stipulates that an automobile must stop 150 feet in front of every wagon, buggy or ox cart, shut off the engine and await the signal to proceed. If this signal is not given the automobile must stand until the animal-drawn vehicle has passed fifty feet to its rear. The rule for overtaking any other vehicle of a non-mechanical nature is that the automobile must remain several feet in the rear and blow the horn. If the signal is given to proceed, the automobilist must not drive by at more than two miles an hour. If no signal is given, he must remain in the rear until a crossroad or some place to turn off is reached. The Chattanooga Automobile Club is working earnestly to have the law amended.

LAKE QUINSIGAMOND, NEAR WORCESTER, MASS.

## HOW THEY CLIMBED THE BIG HILL OF GAILLON

PARIS, Nov. 1.—Though eight years old, the annual romp up Gaillon's smooth-surfaced, precipitous slope has lost none of its attractions. This year the ubiquitous Edge sent a team of cars over—six cylinders, of course—and had no reason to regret his visit to this usually placid corner of Normandy. In the no-limitation speed class Newton, handling a six-cylinder Napier in

30 horsepower—Martin-Lethimonnier triumphed over a De Dion and a Gladiator, in :57 3-5. It was a companion machine to the winner which met with such a disastrous head-on collision in the Criterium of France tour this summer.

After beating all comers, big and little, at Chateau-Thierry a fortnight ago, Olieslaegers, the Antwerp *Red Devil*, had to take the bottom position, owing to the stoppage of a flow of gasoline to the carbureter of his Albatross. Griffon took first and second places in the light motorcycle class, and Alcyon was first in the heavy class, each division providing keen contests.

Eighteen divisions of tourists, from light motorcycles to powerful "sixes," gave a big bunch of winners, but diminished the competitive interest of the classes. Molon's Gladiator, a top-notch at Chateau-Thierry, beat all four-cylinder tourists by climbing the hill in :39 1-5, equal to 56 miles an hour. For a car which took part in Paris-Berlin six years ago and has only five inches bore, this is not bad going. Glenworth, handling one of Edge's six-cylinder Napier cars, made the fastest time of the tourists, irrespective of classes, climbing the kilometer in :33 1-5. Miss Dorothy

HEMERY AND BENZ, FRENCH DRIVER, GERMAN CAR, A WINNING COMBINATION. ■■■

a masterly manner, rushed up the kilometer hill in :26 3-5, an average of 84 miles an hour, beating all comers. Although the Britisher did not lower the kilometer record for this hill, established by Lee Guinness in 25 seconds with the eight-cylinder Darracq of Florida fame, his veteran car made an excellent showing. It was this Napier which established a world's 100-mile record at Florida two years ago, with Macdonald as driver, and made fast time in several Gaillon and Chateau-Thierry climbs. Gore, a familiar figure at Brooklands track, came second on a Mercedes with :31 3-5. Rigal's Grand Prix Darracq came third in :34 4-5, fourth and fifth positions falling to Mors and Rebour. De Lange, in the Darracq built for and victorious in the Sporting Commission Cup at Dieppe this year, captured first position in his own class, time for the kilometer being :57 2-5. Better time was made by the Bayard-Clement Targa Florio racer, which Albert Clement should have driven in Sicily, the kilometer being covered in :48 2-5. These two classes were robbed of much interest through smallness of entries, though the going was always fast.

Germany, Italy, Belgium and France united in the German Emperor Cup class, victory falling to the German Benz, with Hemery at the wheel, in :38 1-5. Fiat, handled by an Englishman, to judge by the name of Johnson, was one minute slower, :39 1-5. Minerva, a Belgian product, took third position, and Rebour and Martin-Lethimonnier, both French, were classed fourth and fifth.

In the Criterium of France class—stock touring machines of about

Levitt, England's champion woman driver, won in her own class with a smaller six-cylinder Napier, time :49, but on general classification was beaten by a number of lower powered four-cylinder cars, among them Berliet, Mors, Gladiator, and Benz. A novelty for a French competition was the appearance of a couple of air-cooled machines; their time was indifferent and did not allow of comparison, each car being in a class of its own.

An unfortunate fatal accident marked the return journey from Gaillon to Paris. Mignot, a young chauffeur, was driving a Regina-Dixi stripped touring car between fifty and sixty miles an hour when the light basket work seat collapsed and he lost control. A tree was struck with tremendous force, the driver being instantly killed and the mechanic slightly injured.

NEWTON'S NAPIER, FASTEST OF THE DAY, DESCENDING HILL ON BY-PATH.

## FRANCE'S SEVEN-DAY RACE OF THE VOITURETTES

PARIS, Nov. 1.—Sixty-three runabouts, representing twenty-eight firms, engaged in the Coupe des Voiturettes, is ample proof that France has come back in earnest to the popular car for the masses. Three years ago the first voiturette contest was held with but a handful of competitors; last year the event was of sufficient importance to be pronounced a success; this year it has reached such proportions that it may rank among the touring competitions of first order.

The modern method of holding a tour—in France at any rate—is to choose a closed circuit and allow the competitors to run round it seven days in succession, the last day being a race for the survivors, the fastest car being the winner. This has been done for the voiturettes, a triangular course, near Rambouillet,

miles. It is impossible to change any important parts, for the main organs are sealed, but ordinary repairs may be performed during running time. Immediately on expiration of time allowance each machine must declare in—or go out forever—and cannot be touched until starting time the following morning. Within the triangular course there is a busy automobile camp, for in addition to the cars staying on the spot for seven days, many of the competitors have gone into camp quarters, notwithstanding that Paris is only thirty miles away.

Six competitors went out on the second day, the trouble being broken gasoline tank, broken cotter pin on a universal joint and resulting complications, broken wrist pin, broken clutch shaft, seized clutch, and one collision. Fifty cars and eleven teams

PREPARING FOR START OF RUNABOUT TOUR ON TWENTY-ONE-MILE BARRICADED CIRCUIT GUARDED BY EIGHT HUNDRED TROOPS.

twenty-one miles round, barricaded at the corners and guarded by troops, has been fixed upon. For six successive days the little automobiles must make seven rounds of the circuit—147 miles—at an average speed of not less than 18.6 miles an hour. For some reason or other the 800 troops supplied from the nearest garrison towns to protect the twenty-one-mile course, arrived late the first day, causing the start to be delayed from 8 A.M. to noon. Impatient at the delay, a number of the drivers rushed round the course at the highest speed possible with their diminutive power plants. As a consequence of their recklessness, one soldier suffered a broken leg, there were a number of narrow escapes, and the "V" turn on the course was more dug up at the end of the first day than the bend at La Fourche on the Grand Prix circuit after speeds of seventy miles an hour. Rigorous orders have now gone forth that any driver covering a round at an average of more than twenty-four miles an hour will be immediately disqualified.

Seven cars went out on the first day, one with a broken shaft, one with a broken driving chain, one with a seized cylinder, one with a bent axle, one with a broken wheel, one through colliding with a tree, and one owing to arriving thirty seconds late on the last round. Late arrival is the only thing that counts against the competitors on this eliminating run of 882

were left to fight for the voiturette trophy. An example of the French system of making rules, to break them, was furnished when one of the competitors was delayed for a couple of hours owing to mechanical troubles. To regain his lost position he had to cover about one hundred miles at an average of thirty-seven per; the single-lunger was only capable of thirty-six miles an hour and consequently arrived a few minutes after the closing of the doors. The rules declared that disqualification would be imposed for exceeding the twenty-four-mile limit.

Three more cars went out on the third day, reducing the competitors to 47, the cause of the abandonment being leaky radiator and seized cylinder; leaky radiator, and a smashed car through missing the turn. Despite the warnings given by officials and the example of those who have succumbed, a majority of the drivers persist in rushing round the course at excessive speed.

Michelin, Dunlop, Continental, and Hutchinson have the stands on the course, but up to the end of the second day had not changed a single tire.

Judging from the characteristics of the sixty-seven runabouts entered for this competition, French constructors are of opinion that the correct thing for a popular two-seater, selling between \$500 and \$600, is a single lunger. Fifty-nine have single cylinders, and eight only are equipped with two-cylinder engines.

ONE-LUNGER BUILT TO RESEMBLE RENAULT RACER.

In every case the cylinders are vertical and carried forward under a bonnet, French ideas of propriety being distinctly against horizontal, double opposed, and engines carried under the body. In last year's test the bore was limited to 120 millimeters, but this year, with one or two exceptions, the bore and stroke of the single cylinders is 3.9 by 4.7, conservatively rated here by some of the makers as 4 1-2 horsepower. Cone clutch and shaft drive predominate, there being but one example of friction disk, and about four cars with side chains. Sliding gears are general, half a dozen of the cars having the luxury of selective type. Ignition by high-tension magneto is the rule, such well-known magnetos as Bosch, Eisemann, Gianoli, and Nilmelior being found on nearly 90 per cent. of the machines. There is but one set of dry batteries in the lot and less than a dozen storage batteries.

While half the cars are fully equipped as sold to the public, the other half are more or less stripped, and some have been modified to give them the appearance of racers. The Passe-Partout team, which ordinarily has a certain resemblance to the Renault, has been modeled closely, by special permission from Louis Renault, to look as much like an offshoot of the Grand Prix racer as possible. The same idea has been carried out with other well-known French racers as models.

#### AUTO NEWS FROM GERMANY.

BERLIN, Oct. 30.—A plan that has found much favor is the introduction of a Russo-Prussian autobus line over the frontier, after the idea of extending the railway from Memel into Russia met with severe opposition from the Prussia Government. A Courland company thereupon approached both Governments as to the advisability of running passenger and goods autos on the Libau-Memel route and received much encouragement from both sides. The chief difficulty is the duty question on the frontier, but it is believed that this will be easily overcome.

Boris Loutzky's marvellous 500-horsepower boat, the Zariza, is just now the main theme of conversation in German circles since its remarkable performances at the Rhine Regatta, when it traveled from Coblenz to Düsseldorf at a mean speed of 51 kilometers per hour and covered the first stretch from Coblenz to Cologne, 97 kilometers, in 1 3-4 hours. Herr Loutzky is one of Russia's most prominent naval engineers and is working at the celebrated Kiel Howaldt Works.

South Germany has not yet given up hopes of having the German autodrome in the Taunus after all, although the powers favor the Eifel project. The Frankfort Automobile Club called a meeting last week, which was largely attended, and named two delegates who are to put their view of the question once again before the Imperial Automobile Club, pointing out in the first place that by erecting the track in the western corner of the Fatherland, France and Belgium would profit almost more than those intended to principally benefit by the scheme, the German manufacturers.

#### FARMAN'S AEROPLANE FLIES 2,529 FEET.

PARIS, Oct. 26.—Henri Farman, a prominent figure in the automobile world during pioneer days, has succeeded in lowering Santos-Dumont's aeroplane record of 721 feet by a flight of 2,529 feet. The aerial trip was made on the open military ground at Issy-les-Moulineaux, near Paris, in the presence of a large number of spectators. After a few preliminary runs against the fresh southwest wind, Farman started his 50-horsepower Antoinette motor again and rushed over the ground at twenty miles an hour. After a sprint of one hundred yards the front horizontal rudder was raised to a slight angle and the big machine lifted into the air to a height of nearly ten feet. The rudders were skillfully adjusted and it was at this height that the official measurement was taken by representatives of the Aero Club of France. The official time for the flight is announced as fifty-three seconds. Farman has made at least half a dozen flights of over six hundred feet during the past ten days, each one in the presence of a large number of spectators. No attempt is made at secrecy, his training ground being an open field used by the artillery brigades and open to the gaze of all passersby. Santos-Dumont and Wilbur Wright are among those who have witnessed the flights.

Henri Farman's record-breaking aeroplane has few new principles, its designer having simply sought to work on the lines of Delagrange, Santos-Dumont and others, and modify details. It consists of a forward cell 33 feet in width united to a rear cell of about 20 feet. A couple of bicycle wheels under the forward cellular planes and one under the rear planes serve to support the machine on the ground for the initial speed of twenty miles an hour necessary to obtain flight. The Antoinette 50-horsepower motor is carried on the forward plane, where it drives a two-bladed propeller calculated to propel the machine at a speed of 32 miles an hour. The eight-cylinder engine is of the latest model with water-cooled cylinders.

#### SANTOS-DUMONT HYDROPLANE HAS SETBACK.

PARIS, Oct. 26.—Santos-Dumont has launched his novel hydroplane, designed to attain a speed of over sixty miles an hour, but failed to create a very good impression in the first tests on the Seine, near Paris. With minute care the tender machine was placed in the water. Santos-Dumont, attired in a leather suit, took his place behind the steering wheel at the end of the central cigar and the curious craft was towed out to midstream. The sixteen-cylinder motor was new and could only be started up after a long delay. When the three-bladed propeller finally did begin to revolve the boat traveled 350 yards, then came to a dead stop. Even when under way the craft seemed lifeless and refused to glide over the surface as her designer had expected. After an hour the boat was withdrawn, Santos-Dumont declaring that failure was due to the engine turning only at 800 revolutions instead of 1,500. Before making any further attempts on water, he will carefully tune up the engine, being convinced that with sufficient power he can travel 60 miles an hour.

FARMAN AEROPLANE IN ITS RECORD HALF-MILE FLIGHT.

## LETTERS INTERESTING AND INSTRUCTIVE

### HOW MUCH POWER IS USED IN TURNING OVER?

Editor THE AUTOMOBILE:

[951.]—Will you please inform me, either through "Letters Interesting and Instructive," or otherwise, the horsepower or fraction thereof required to produce a revolution of a 50-horsepower gasoline motor? Would the compression per square inch affect this figure; in other words, would it require greater power to produce a revolution of a 40-horsepower motor with, say, 70 pounds compression to the square inch, than a 50-horsepower motor with perhaps only 60 pounds compression to the square inch? H. C. ARNOLD.

South Framingham, Mass.

It has been found by extensive experiment and investigation that the horsepower consumed by a well-built steam engine of the simple type, in overcoming the friction of its own moving parts, is about 5 per cent. of the total power generated. With the exception of the factor of compression, this may doubtless be found equally applicable to the internal combustion motor, though the latter has an advantage in this respect over the steam engine in that it has no glands or stuffing boxes on its moving parts. If we assume this as a basis for calculation, also that the 50-horsepower motor is well built and properly balanced, it will follow that 2.50 horsepower are consumed in turning the engine over when running at its full capacity, although it has been established that the friction in an engine is practically constant at all loads. However, it naturally increases rapidly with the speed, but it may be assumed that the motor in question turns over at the rate of 1,000 r. p. m. when running under full load. Then the power consumed per revolution

2.50  
in turning such an engine over would be  $\frac{\quad}{1000} = .0025$  horse-

power. This ignores the factor of compression completely. It naturally requires more power to compress a given volume to 70 pounds pressure than it does to 60 pounds, but the comparison you make involves differing volumes, or at least may be assumed to do so owing to the difference in the power of the motors. As the term horsepower involves three essential factors, *viz.*, m. e. p., or mean effective pressure throughout the stroke; area of piston acted upon and the speed of piston travel, it may be that the 50-horsepower motor would require less power to turn over per revolution than the smaller one, though this does not naturally follow. If, through errors of design, it was necessary to compress the same volume in the smaller motor to 70 pounds per square inch to obtain 40 horsepower, as was employed in the larger motor to give 50 horsepower at 60 pounds pressure, it is obvious that more power was being wasted in the smaller motor and it would consequently require more per revolution.

### CONCERNING VALVE-GRINDING AND RESEATING.

Editor THE AUTOMOBILE:

[952.]—Some time in the past year you had an article in "The Automobile" about grinding and reseating valves. Will you kindly give me the date of the issue in which this article appeared, and very much oblige? J. B. SEEGER.

Dallas, Tex.

We do not recall that any extended article on this subject appeared in THE AUTOMOBILE during 1906. The only thing of the kind revealed by our index is entitled "A Wrinkle in Grinding Valves," in the issue of August 23, 1906. This was merely a paragraph and advocated the use of a piece of emery cloth in the shape of a disk slightly larger than the diameter of the head of the valve, a small hole being made through the center of the disk to pass the valve stem. This expedient is recommended where pitting is to be removed and is followed by the usual grinding in with flour emery and oil. We do not know of anything else that appeared on this subject during the period in question, but would be pleased to help you out through this department to the extent of our ability.

### CRANKSHAFT DESIGN IN TWO-CYLINDER MOTOR.

Editor THE AUTOMOBILE:

[953.]—Would you be kind enough to inform me through the columns of your paper what the serious objections are to having two cranks on a two-cylinder upright engine on the same line with each other, so that there would be an impulse every revolution, instead of two impulses one revolution and none the next, which is the case with cranks opposite? Of course, I recognize the fact that the pistons, rods, and cranks are unbalanced, but would not the heavy flywheel which is necessary to carry the engine over one complete revolution take care of this and one impulse every revolution would make a more powerful and less jerky motor? Did you or any of your many readers ever have any experience with a crankshaft made this way? CURIOUS.

Brooklyn, N. Y.

The chief objection to building a two-cylinder motor with this type of crankshaft is to be found in the fact that it is impossible to accurately balance it mechanically, and this is found to be of more importance than the impulse balance. However, such motors are not as rare as your question would seem to imply. In fact, most stationary motors are built in this way and a great many automobile engines have also been equipped with crankshafts having the pins in the same plane, the 180-degree placing having been an exception up to within quite recently. The latter offers greater advantages for automobile work, as it obviates the necessity of providing heavy counter-balance weights, and even with these an accurate mechanical balance is not obtainable. The flywheel does not compensate for this entirely, while it does tide the motor over the idle interval very effectively and there is no jerky effect such as you imagine, the power being unaffected in either case. You will find in the two-cylinder Brush runabout an example of this type, but special pains have been taken to balance the motor by providing a counter-weight on an auxiliary shaft.

### "WHY SO MUCH 'KNOCKING' IN THE AUTO TRADE?"

Editor THE AUTOMOBILE:

[954.]—I want an automobile and have wanted one for a long time, but the dealers have kept me from buying, and I have no doubt they keep a good many would-be purchasers from buying in the same way. For instance, I like the looks of the Reo and when I tell the Maxwell agent this he says, "You make a big mistake in buying a one-lunger. The minute that one cylinder goes out, you are done for. Take my advice and get a two-cylinder car." I go to the repair man and ask him if the Ford isn't a good little car. He says they are in the shop all the time and the cost of upkeep is very high. The repair man recommends some other car, and when I ask some one in regard to the make, he promptly "knocks" it and urges me to buy something else. I have about come to the conclusion that all cars are either junk or else all the trade are liars. Why it is that there is so much knocking in the automobile business? Many a man is kept from buying a small car through the talk given him by the trade of the awful size of the repair bills he must expect. Now, in view of the accounts published by owners of the steady service given by their cars, either these accounts are fabrications or else the trade is doing a lot of costly knocking. It is to be presumed that the dealers want to sell as many cars as possible, therefore, why don't they try to interest a prospective autoist by telling him that the car he favors is a very reliable car, but that he believes the car he represents would be more suitable. In this way, some one would sell the man a car and make one more convert for good roads—a thing much desired by all. Is it really true that, no matter how carefully it is handled, all cars require constant repairing and replacements? Looks to me from the dealers' talk that the first cost isn't anything compared to the cost of upkeep. H. E. REKOOT.

San Francisco, Cal.

We heartily agree with you that the practice of "knocking" the other fellow's car at every opportunity which prevails is much to be deplored. Unless he be so credulous as to gulp such statements entire, it belittles the dealer in the prospective buyer's eyes and when oft repeated is apt to disgust him entirely. It is not confined to the automobile business by any means, but as you say, it is an extremely shortsighted policy that does an infinite amount of harm—to the dealer himself, in the first instance, and

to the cause of automobiling and good roads ultimately. When a man is trying to sell you cabbages, or what not, he does not take pains to tell you that his wares are rotten, and the other fellow's the best in the world; it is the other way round, and in the last analysis it is merely human nature. The seller invariably puffs his own goods and deprecates the idea of buying from anyone but himself. But take some of the loudest of these "knockers" to task and ask him to substantiate his accusations: in nine cases out of ten he has absolutely nothing to back his statements but his own anxious desire to make a sale. While this is commendable, selling goods at the cost of belittling and berating the goods of his competitor is far from it.

All cars and all machinery require repairs and replacements, but this need should be far from constant, if they be properly taken care of, nor should the expense of maintaining any of the cars you mention exceed 10 to 15 per cent. of their first cost during the first year. There are any number of cases where it has not been 5 per cent., or even less. The accounts published from time to time of moderate upkeep expenses are not imaginary, often being substantiated by verification before a notary and being the actual experiences of autoists who take care of their own cars the year round. All cars go wrong at times, and any car, recklessly and improvidently handled, will run up a pretty bill of expenses. One or two such instances may form the foundation for a tremendous amount of the "knocking," but the very dealers who have been doing it were, at the same time, concealing skeletons as bad, if not worse, in their own closets.

#### RELATIVE EFFICIENCY OF TWO AND FOUR-CYCLE.

Editor THE AUTOMOBILE:

[955.]—Will you please give me some information concerning the relative efficiencies of the two and four-cycle gasoline motors? What are the chief objections to the use of the auxiliary exhaust port in a four-cycle motor? Has the carbon which is contained in gasoline or kindred fuels any value as a power factor in the operation of an explosion motor? Can you give any more information concerning the double acting motor described on page 96 in "The Automobile," July 18 issue? Although living in the same city (Denver, Colo.) as the address of the Fish Gas Engine Company. I am unable to locate them or anything connected with the creators of this seemingly nine-day-wonder, which to the skeptical-minded certainly looks "fishy," at least.

G. I. PETERSON.

Denver, Colo.

We believe that carefully conducted tests have shown the relative efficiency of the two and four-cycle engines to be about 10 per cent. in favor of the four-cycle.

We do not know that there are any serious objections apart from the additional mechanism involved, as it is necessary to open the valves of an auxiliary exhaust positively.

Carbon is the basic combustible element in practically all fuels, whether liquid or solid. Gasoline and similar fuels are hydro-carbons, meaning that they consist principally of hydrogen and carbon.

We have no further data concerning the motor in question than appeared in the description you referred to, but the names of the builders were given there, and we believe addressing them at Paris, France, or care of one of the French papers, such as *L'Auto*, would reach them.

We cannot help you out on the last question as the only information we had on the matter was contained in the communication of our correspondent.

#### CREDIT FOR THE FIRST SIX-CYLINDER.

Editor THE AUTOMOBILE:

[956.]—There is a great deal of talk going the rounds, edited by various factory representatives, agents, etc., claiming in each case that the credit of having produced the first six-cylinder automobile in America belongs to the particular company with which they are at the time connected. To those who know some facts in connection with the past production of the six-cylinder motor, the many claims emanating from the hustling agents bring forth a series of "rippling smiles!"

There are many who claim the added complications of the six do not offset the claim for greater elasticity made for it, etc.

Here is the difference in figures, showing just how much more elastic the six-cylinder engine is over the four-cylinder, as ascertained by actual running, which, after all, is the only convincing proof. The six-cylinder car can be throttled down to 33-4 miles an hour. The four-cylinder car can be throttled down to four miles an hour on high gear. The difference in one hour's running is 1-4 mile. At this game, is there much gained? The pulsation of the four-cylinder motor is no more perceptible to the passengers at four miles an hour than it is to the passengers in a six-cylinder at 33-4 miles an hour; the riding qualities are the same.

Another natural source or productive cause of easier riding claimed for the new sixes has arisen in the enforced increase of wheelbase, due to the room demanded to take care of the six cylinders. There are manufacturers of fours that have always made it a point to give a generous wheelbase. There is nothing so conducive to easy riding as a long wheelbase.

At ten miles the 1908 four-cylinder, long wheelbase car runs every inch as smoothly, as quietly, as any six-cylinder, with the added virtue of having fewer working parts. It has been a struggle to reduce the number of working parts in the modern auto. In the fours it has been accomplished; in the sixes, the working parts have been increased. It is a situation taken in at a glance by either the expert mechanical genius or the layman.

To go back to the question, "To whom should the credit go for the production of the first six-cylinder car in America?" don't all speak at once! One at a time, please! Was it Winton? Was it the Pierce Company? Was it the Oldsmobile? No! Well, then, who was it?

In 1904, at the Madison Square Garden show, the E. R. Thomas Motor Company had on exhibition a six-cylinder chassis which had been run successfully, and was offered for sale at \$6,000, and was rated at 60-horsepower. At that time there was no purchaser; the idea was too much for the embryonic automobilist of that day.

After a lingering state of coma in New York, the "Big Six" was returned to the factory, and was next heard from when M. Roberts, Harry S. Houpt's driver, qualified with it in the Vanderbilt race, on the Long Island course in 1905, making good time.

We will permit the reader to judge for himself. "Who produced and offered for sale the first six-cylinder car in America?"

S. F. Edge, the English champion of the six-cylinder car, followed Mr. Thomas' footsteps one year later.

FRED J. TITUS.

Newark, N. J.

#### WHAT ONE OHIO BUGGYABOUT DID.

Editor THE AUTOMOBILE:

[957.]—A few words may not be amiss regarding the Hatfield buggyabout, and what it will do when called upon.

October 10, Mr. Hatfield, Sr., and Mr. Zent, the master-mechanic of the Hatfield Motor Vehicle Company, left Miamisburg, Ohio, at 8:30 a. m. and arrived in Cincinnati at 11:15 a. m.—a distance of 49 1-2 miles. This trip was made without a stop of any kind, and every hill, with the exception of two, were taken on the highest speed. The roads were very heavy and muddy, and, as every one who is familiar with the country knows, it is a miserable proposition for automobiles.

After arriving in Cincinnati, Mr. Zent and a member of the Chas. Behlen Son's Company ran down to the river front and then ran straight up the hill and then up to the top of the Vine street hill, and also took in McMicken avenue. To any one who is familiar with the streets of Cincinnati and its cobblestone pavements it will appear that the car does all it should do. One hill climbed in Cincinnati we consider the worst hill in the State of Ohio.

On the unlucky day of the thirteenth of October, C. B. Hatfield, Jr., secretary and treasurer of the company, accompanied by Clay T. Vance, vice-president, drove the Hatfield buggyabout from New York City to Camden, N. J.—102 miles—in 5 hours 40 minutes, without a stop, having been obliged to slow down to the rate of seven miles an hour through seventeen towns. In the very near future a record run from Miamisburg to Indianapolis, Ind., will be made by the way of Dayton, Ohio—a distance of 122 miles.

Miamisburg, Ohio.

C. B. HATFIELD.

#### FOR THOSE TOURING INTO CANADA.

Editor THE AUTOMOBILE:

[958.]—Some three weeks ago I telephoned you for information as to the proper person to whom I could apply at Rouse's Point for the papers and license necessary in taking my automobile into Canada. I write to thank you for the trouble you took in the matter, and to say that, from my experience, F. W. Myers & Co., of Rouse's Point, N. Y., are a firm to whom you can refer any automobilist, with the assurance that he will receive prompt and courteous attention. If he owns an imported machine, have him obtain a certificate from the collector of the port of entry that duty was paid, as he will need it at the Canadian line.

MACOMB G. FOSTER.

New York City.

TYPE XVII, FIFTY-HORSEPOWER POPE-TOLEDO TOURING CAR

**P**OPE-TOLEDO practice as exemplified by the new Type XVII, 50-horsepower car, which will be one of the representatives of the line for 1908 made by the Pope Motor Car Company, Toledo, O., is characterized throughout by the many numerous special features of design and construction which have been identified with it for the past two years. The motor is distinguished by the use of copper water-jackets surrounding the twin cylinder castings and large valves set at an angle in the cylinder heads and operated by walking beams from the single camshaft and set of cams. The exhaust valves are operated by individual springs, while the inlet valves are provided with supplementary stems, which can be removed for adjustment or replaced, thus preventing any danger of having the valves thrown out of alignment by reason of a warped stem. Specially treated chrome nickel steel is the material employed for the crankshaft, wristpins and connecting-rods, the first-named being supported on three liberal-sized D. W. F. annular ball bearings.

**Motor Accessories.**—In accordance with recognized standard practice on the highest grade cars, dual ignition is fitted, an Eisemann high-tension magneto and non-vibrating coil being provided to take care of the running side of the duplicate system, while a standard four-unit coil and accumulator set with primary timer run by the motor complete the other side. Instead of being placed on the dash as usual, the coils are carried under the front seat of the car, while the accumulators are housed in a special steel case carried on the running board. Either system can be used independently or both together, and the purchaser is given an option of the Bosch high-tension magneto for the running side where this make is preferred.

The carbureter is an exclusive Pope-Toledo design and is of the annular float type, insuring a constant supply of fuel regardless of the position of the car. While the main fuel supply is maintained by means of an ingenious pressure system in which a simple pump automatically operated by the exhaust pressure raises the gasoline from the 26-gallon copper tank at the rear of the car, the feed to the carbureter is on the gravity principle. This is ac-

complished by placing an auxiliary one-gallon tank on the dash, in which the fuel is kept at a constant level as long as the car is running. An auxiliary hand-pump is provided for emergencies, none being required for starting, as in the usual pressure system, owing to the supply in the small tank. The carbureter has a wide range of flexibility and will run the motor from about 200 r.p.m. to 1,200 r. p. m. with great efficiency. The water pump is centrifugal and gear-driven, carried on the forward end of the engine, and has a liberal capacity. It supplies the special "planetic" radiator of exclusive design and which is made in the home plant. This is of novel principle and construction and gives a high efficiency, thus necessitating a minimum quantity of water. A high filling thimble and a hard rubber vulcanized cap lined with brass are fitted, the latter being convenient to handle while the former prevents the hot water from siphoning from the radiator. Lubrication is of the continuous circulating type, using a gear pump run from the camshaft and a three-gallon tank.

**Transmission Essentials.**—The first step in the transmission of the power consists of a multiple-disk clutch of special design, and which, contrary to usual practice where this essential is concerned, is encased in the same housing as the gear-set instead of being made a part of the flywheel. Packing joints providing with gland nuts are placed between the case holding the change-speed gear and the clutch and between the clutch and the outer end of the shaft, thus making the clutch case absolutely oil-tight. The number of disks has been reduced and their shape changed as well, permitting quicker action while still retaining the extremely smooth operation of this type. Hand holes have been provided for examination and oiling. The change-speed gear is of the sliding type with selective operation and provides four speeds forward, the direct drive being on the third. Chrome nickel steel is used entirely for both shafts and pinions, the former running on D. W. F. annular ball bearings of large size, the whole running in a liberal supply of oil. The entire clutch and gear-set unit is located directly back of the flywheel, which brings the former in a very accessible position beneath the

CAMSHAFT SIDE OF MOTOR, SHOWING CARBURETER AND MAGNETO.

POWERFUL CONSTRICTING BRAKE ON DRIVING SHAFT.

STEERING KNUCKLE AND RADIATOR CONSTRUCTION.

footboard; a large hand-hole and screw top are provided to permit access to the interior. The differential case on the center of the jackshaft has also been provided with liberal sized hand-holes for adjustment and lubrication. Final drive is by double side chains to the rear wheels, the chains themselves being of the silent type, the material employed being chrome nickel steel. The few disadvantages of this type of drive are entirely obviated by the provision of special chain cases, thus insuring cleanliness and efficient transmission of power at all times. Particular attention has been paid to making every part of the transmission, right from the flywheel back to the drivers, as accessible as possible, while still maintaining the highest standard of efficiency throughout.

**Chassis and Running Gear.**—The frame is of the inverted "U" type with reinforced edges that has long been a distinguishing feature of the Pope-Toledo design. It is amply stayed and braced by transverse members and gussets, the former carrying the transmission unit. The axles are of I-beam section of generous size and of chrome nickel steel, the front being provided with pivots and steering knuckles mounted on D. W. F. annular ball bearings, with hardened steel bushings and compression grease cups, an excellent idea of the construction of this part of the car, as well as of the special type of radiator employed, being illustrated in one of the accompanying photographs.

Thirty-six-inch artillery wheels shod with 4-inch tires front and 4 1-2-inch rear complete the running gear, and these, in connection with the liberal spring equipment, which is of the semi-elliptic type, provide extremely easy riding. The matter of tire equipment is left entirely to the purchaser, the option of any of the best-known American makes being given.

That most important of all parts of the car—the

brake equipment—has come in for special attention, and it is doubtful if there are many cars on which it has been considered as of such extreme importance as on the Pope-Toledo. The running brakes are located in dust-proof drums on the rear wheels, being operated by a pedal which interlocks with both the clutch and the emergency brake hand lever on the side of the car. The emergency brake is of unusually powerful dimensions and is placed on the driving shaft between the gear-set and the differential. It is operated independently of the clutch by means of a second pedal, this arrangement facilitating restarting when stalled on a steep grade.

A pressed-steel body trimmed with Cuban sabique completes the car, a great deal of attention having been lavished on the body design with a view to providing the maximum of comfort and convenience for the passengers. A locker under the forward seats and opening into the tonneau provides accommodation for two dress-suit cases, while further space for baggage is provided under the rear seats. Tools, oils and accumulators are all carried in special steel boxes attached to the running boards, the tool box also accommodating the tire necessities. The car is listed both as a touring or roadster type and a new design of body has been made for the latter. The hood and guards are all of aluminum with reinforced steel edges.

COMBINED CLUTCH AND GEAR-SET UNIT.

SIDE ELEVATION OF THE COMPLETE POPE-TOLEDO CHASSIS FROM THE EXHAUST SIDE OF MOTOR

## CONCERNING THE KNOX WATER-COOLED MOTOR

**T**HOUGH in his first attempts the American maker followed the standards set up by previous stationary practice rather closely, he seldom went as far as adopting the two-piece cylinder construction that is still prevalent in that field. Instead, he made

make for simplicity, using this term both from the user's as well as the maker's point of view. The most prominent of these, as already mentioned, is the two-piece cylinder construction. Separate cylinders are employed as usual, each consisting of two

THE NEW KNOX MODEL L WATER-COOLED MOTOR FROM THE EXHAUST SIDE.

one-piece cylinder castings, and the latter have become practically universal in automobile motor practice, until now, the first signs of a tendency to return to former standards are revealed in the design of the Knox water-cooled engine, which forms the power-plant of the new Knox Model L car for 1908. So far as the car itself is concerned, it is a replica of those distinguishing features of design and construction that have long been identified as Knox standards and so may be said to depart little from the cars built by this concern — the Knox Automobile Company, Springfield, Mass., for several years past. The chief departure is naturally that of the adoption of water-cooling, and even in the design of the water-cooled motor, the same Knox standards that have become familiar on the air-cooled type of motor have been closely adhered to, so that, taken all in all, it is practically only in the provision of a radiator and the other essentials of water-cooling that the new motor differs.

When considered in detail, however, the motor itself is found to embody more than one instance of what may be termed advanced practice in that they

no cages being employed, but instead of being placed in two lines as in the air-cooled motor, they are located on a single line lengthwise of the four units. Liberal provision for water is made in the head, the valve seats being cored in so that both

castings, one forming the body of the cylinder and the other the head. The most noticeable thing about these castings, and it is a feature that overcomes the old and well-founded objections to the use of two-piece cylinders, is the fact that both the cylinder proper and the head have each an independent water-jacket, with very liberally proportioned water spaces. The cylinder jacket covers it entirely but is closed at the top, the inlet being at the bottom and the water again issuing at a point diagonally opposite. Thus there are no water joints which could occasion a leak into the cylinder. In machining the cylinder casting a counterbore is made at its upper end on the outside, leaving a protruding shoulder or ring. In assembling, an asbestos-copper gasket is placed on this shoulder and the correspondingly recessed cylinder head seated upon it. The valves seat directly in the head,

WORKING SIDE OF THE KNOX MOTOR, SHOWING VALVE MECHANISM AND CONNECTIONS.

CYLINDER AND VALVE ASSEMBLY OF THE NEW KNOX MOTOR.

are entirely surrounded by the circulating water. Although the jackets are entirely independent, the circulation is continuous, as the water, after rising through the cylinder jacket proper, is transferred to the head by means of a small U connection clamped on, the hot water issuing from the top of the head at the right side. This form of construction permits of machining the entire combustion space, besides making a much simpler casting. Shoulders are cast on each corner of the cylinder proper, and into holes tapped in these, studs are screwed. The latter coincide with holes drilled in the cylinder heads which are held down by four nuts, it being impossible to bring the parts together without a correct bearing. The valve mechanism is all on the right-hand side of the motor and is actuated by a single camshaft. The engine design is such throughout that the air-cooled cylinders may be substituted with little difficulty.

The advantages of this form of construction will be apparent at a glance. The head may be removed merely by taking off four nuts, thus giving access to the entire interior of the combustion chamber and making the task of cleaning the latter of carbon deposits quite an easy matter when compared with the standard type, in which the entire cylinder must be lifted from the crankcase. It also facilitates grinding in the valves and this may be done without any danger of having the grinding compound get into the cylinder. Disconnecting the big end of the connecting rod permits of the ready removal of the piston for inspection and also makes it a far easier matter to reinsert the latter with its rings when reassembling the motor.

ESSENTIALS OF THE KNOX WATER-COOLED CYLINDER.

### ALL KINDS OF AUTO MAKING IN MICHIGAN.

Tolmy Hill, of Cherry Valley township, Lake county, Mich., has invented an automobile more wonderful than Holmes' wonderful one-horse shay. He has just been exhibiting his machine at one of the Michigan fairs, and "By heck," it goes.

The specifications of this new model of horseless carriage are: A second-hand brake wheel; a second-hand ice cream freezer, constituting a water tank for cooling the engine; a second-hand gasoline can; a second-hand marine engine; a new "sparker" costing \$21; a second-hand set of farm wagon wheels; a second-hand set of gears from a marl mixer, and a miscellaneous assortment of junk, all second-hand.

Does she go? You'd better guess. One facetious spectator at the trial test said that she made six miles a week. But the judges' stop watches showed a mile in 8.76 minutes. There are three speeds to this latest type of auto, three, eight, and fifteen miles an hour, though Mr. Hill admits he has tried the fifteen-mile gear only once.

"She splashed water all over me then," said he, "but she went two miles at that clip."

At the last fair which he visited this carriage had the honor of carrying several notables around the race track, including

TOLMY HILL, OF CHERRY VALLEY, MICH., AND HIS CAR.

Governor Warner, Lieutenant-Governor Kelley and Congressman Townsend. He made it in 8.76 flat, amid the cheers of the crowd.

Tolmy Hill, the author of this contraption, is an old man who earns his livelihood by working in the marl mill at Marlborough. He may not be a millionaire, but he has a mighty good time in the world, and the assembling of the parts to his 1908 model has been one of his greatest pleasures. "And, by heck, she runs."

### HOW A MOTORPHOBE JUDGE WENT WRONG.

ALBANY, N. Y., Oct. 21.—That prejudice may sometimes overreach itself to its own undoing, has seldom been better illustrated than in the case of Justice J. P. Van Ness, of the Court of Special Sessions, East Greenbush, who has achieved considerable of a local reputation as a motorphobe. Howard A. DeGraaf was arrested for exceeding the speed limit on October 28, 1906. He was taken before Van Ness, sitting as a justice of the peace, and fined \$25, which he refused to pay, giving \$100 security to appear before the same justice sitting in the Court of Special Sessions several days later. He was there fined \$100, and again refused to pay it, taking an appeal. Under the Code of Criminal Procedure, the jurisdiction of this court does not extend to fines in excess of \$50, although the Motor Vehicle Law authorizes a fine to that amount. Justice Tierney, sitting in the Rensselaer County Court, has just reversed the decision on this ground, and as the Court of Special Sessions is not a court of record, there is no provision in the code for remitting a case to it for retrial on reversal, and De Graaf escapes.

TWO VIEWS OF THE SOUTH CAROLINA STATE HIGHWAY.

The upper picture shows the sand bed which belied the name of road, and the lower view shows the same course after improvements were completed.

CHARLESTON, S. C., Nov. 4.—As the result of much agitation in the form of automobile runs, petitions and public mass meetings, thus bringing to the notice of the authorities the poor condition of the roads around Charleston, the people of this county have succeeded in getting an appropriation and the right to use convict labor to convert the present sand beds called roads into modern macadam highways.

In January last the State Legislature elected a committee of prominent men to act as special highway commissioners, and the first move of the commission was to plan and lay out a fine highway to Summerville, the well-known winter tourist resort, about 25 miles from Charleston. Three routes were available, and after careful consideration of their advantages as set forth by those interested in each route, the making of many auto trips over each, and close studying of the actual surveys of each route, the committee chose the original State road going over to Summerville by way of Otranto. This road for miles has long held the reputation of being the worst sand bed in this section, and has taxed the ability of more than one car in passing through it.

In choosing the best materials and methods to build the road, the committee received valuable assistance from the United States naval station, situated on the Cooper river at Charleston, Commandant Dyer having made extensive experiments in that line in building the roads through the United States Government reservation. Augusta gravel or cement gravel, a natural mixture of clay, pebbles and coarse gravel, was chosen, this having given much satisfaction in Georgia at Savannah and other places, and having shown the best tests here.

The new road runs straight north from Charleston by way of Meeting street, considerable progress in the building of it having been made already, so that by next Spring it is expected that visiting autoists and tourists at Summerville will be able to run to Charleston over a beautiful highway through the fragrant pine-lands and at as high a speed as they can reasonably wish. The committee is now contemplating the plans of improvement on the other roads leading to the rich truck farming districts, and to the great sea island cotton centers, so that in a few years this country will have many miles of fine roadway.

The autoists in this section, having become a very strong factor, are to be thanked for this good roads agitation. The percentage of automobiles in Charleston has increased 200 per cent. in the last eight months, and over 100 have taken out licenses with the clerk of the court. There are more than 100 automobiles in Charleston, but only this number has been registered. In a few months, at the present rate of increase, there may be 200 machines registered.

#### COLUMBIA AUTOISTS FOR GOOD ROADS.

COLUMBIA, S. C., Nov. 4.—An automobile organization for the improvement of roads in Richland county was recently organized at a meeting of automobilists at the Ridgewood Club. The meeting was very largely attended, and there was a general discussion, which culminated in the formation of a permanent organization with the following board of officers: President, E. M. Whaley; vice-president, G. M. Berry; secretary, W. C. Swaffield; treasurer, T. H. Meighan.

F. H. Hyatt made an address on the necessity for road improvement and advised the appointment of a committee to work in harmony with the general organization recently formed in Columbia for road improvement in the county, and President Whaley, Secretary Swaffield and H. D. Lorick were named such a committee to appear before the grand jury and invite that body to take a ride over some of the roads in order to better understand their condition. A committee on constitution and by-laws consisting of R. L. Moore, B. F. McMasters, S. M. Harman, C. M. Lide and C. T. Jones was appointed.

#### TEXAS AUTOISTS WORKING FOR HIGHWAYS.

BEAUMONT, TEX., Nov. 2.—Arrangements have been completed by a number of representative citizens owning automobiles in this city with J. C. Chaney, the county commissioner, under authorization from the county commissioners' court, for grading, putting in abutments to bridges, and otherwise improving the

HOUSE AND GROUNDS OF CHARLESTON COUNTRY CLUB.

THE OAKS—A COUNTRY HOME NEAR CHARLESTON, S. C.

Collier's Ferry road, leading from the city limits to Collier's Ferry, where the Beaumont Country Club has its house.

Under the arrangement which has been made, the county will defray one-half the cost of the improvements, and the other half is to be paid by the automobilists, who will be greatly benefited by the work. A liberal amount of money has already been subscribed, and work has been commenced by the contractors.

### GOOD ROADS TALK ALONG THE MISSISSIPPI.

MEMPHIS, TENN., Nov. 4.—In spite of the fact that roads in this section of the country, and particularly from here southward, are as far from being what they should as it is possible to imagine, and still dignify them by the name of highways, the interest in automobiles and automobiling has been experiencing a marvelous growth during the past two years. As is the case wherever the automobile takes hold, the talk of good roads immediately becomes prevalent and there is every prospect that the benefit of its influence will soon begin to assume definite form. Local organizations do their utmost to further the movement, but naturally their capacity in this direction is limited, usually being confined to roads in the immediate neighborhood. Among the numerous projects in the way of road improvement is the proposal to utilize the tops of the levees along the Mississippi as automobile roads, and the scheme is not as fanciful as it may appear to some.

HIGHWAY COMMISSION MAKING PLANS TO WIDEN ROAD.

## THE AUTOMOBILE CALENDAR. AMERICAN.

### Shows and Meetings.

- Nov. 9-16.....—Philadelphia, First Regt. Armory, Automobile Show, Philadelphia Automobile Trade Association.  
 Nov. 16-23.....—Baltimore, Third Annual Automobile Exhibition, Automobile Dealers' Association. B. R. Johnson, manager, Piper Building.  
 Nov. 30-Dec. 7.—Chicago, Coliseum and First Regt. Armory, Eighth Annual National Automobile Show, and First Annual Commercial Vehicle Show, National Association of Automobile Manufacturers.  
 Dec. 9-15.....—Detroit, Riverview Park Auditorium, Detroit Automobile Dealers' Association. LeRoy Pelletier, manager.  
 Dec. 14-21.....—St. Louis, Mo., New Coliseum, Second Annual Auto Show, St. Louis Automobile Manufacturers' and Dealers' Association.  
 Dec. 28-Jan. 4.—New York City, Madison Square Garden, Importers' Salon. C. R. Mabley, manager.  
 Feb. 10-15.....—Detroit, Light Guard Armory, Tri-State Automobile and Sporting Goods Association, Seventh Annual Show.  
 Mar. 7-14.....—Boston, Mechanics' Building and Horticultural Hall, Boston Automobile Dealers' Association. Chester I. Campbell, manager, 5 Park Square.  
 Mar. 9-14.....—Buffalo, Convention Hall, Sixth Annual Automobile Show, Automobile Club of Buffalo. Dal H. Lewis, manager.  
 Mar. 21-28.....—Toronto, Canada, St. Lawrence Arena, Automobile Show. R. M. Jaffray, manager.  
 Apr. 5-12.....—Montreal, Canada, Arena, Third Annual Automobile and Sportsman's Show. R. M. Jaffray, Mgr.

### Motor Boat Shows.

- Dec. 7-14.....—New York City, Grand Central Palace, National Association of Engine and Boat Manufacturers. Chester I. Campbell, manager, 5 Park Square, Boston.  
 Jan. 1-8.....—Chicago, Coliseum, National Association of Engine and Boat Manufacturers. Chester I. Campbell, manager, 5 Park Square, Boston.  
 Jan. 25-Feb. 1.—Boston, Mechanics' Building, National Association of Engine and Boat Manufacturers. Chester I. Campbell, manager, 5 Park Square, Boston.  
 Feb. 3-8. '08....—Buffalo, Convention Hall, First Annual Power Boat and Sportsman's Show, auspices of Buffalo Launch Club. Dal H. Lewis, manager.  
 Feb. 20-Mar. 7.—New York City, Madison Square Garden, Fourteenth Annual Motor Boat and Sportsman's Show.

### Races, Hill-Climbs, Etc.

- Nov. 15-16.....—Newark, N. J., 24-hour Endurance Run, Automobile Club of New Jersey.  
 Nov. 26-28.....—Chicago, Three-day 600-mile Reliability Race, Chicago Motor Club.

## FOREIGN.

### Shows.

- Nov. 11-23.....—London, Olympia Motor Show.  
 Nov. 12-Dec. 1.—Paris, Exposition Decennale de l'Automobile, Grand Palais, Esplanade des Invalides, Automobile Club of France.  
 Nov. 22-30.....—London, Agricultural Hall, Stanley Show.  
 Dec. 5-22.....—Berlin, Germany, Automobile Show.  
 Dec. 21-Jan. 2.—Brussels, Show, Palace of the Cinquantenaire.  
 Jan. 18-Feb. 2. '08—Turin, Italy, Fifth International Automobile Exhibition, Palace of Fine Arts, Valentino Park, Automobile Club of Turin.  
 Mar. 21-28.....—London, Agricultural Hall, Cordingley's Show.

### Races, Hill-Climbs, Etc.

- Dec. 8.....—Paris, Straightaway Aeroplane Speed Test, auspices of "L'Auto."  
 Dec. 13.....—Paris, Competition for Agricultural Automobiles, auspices of "L'Auto."  
 May 12, 1908....—Sicily, Targa Florio, Automobile Club of Italy.  
 June 20-July 5.—Grand Prix, Dieppe Circuit, Automobile Club of France. (Exact date to be announced.)  
 August, 1908...—France, Coupe de la Presse, Automobile Club of France. (Exact date to be announced.)

# ACETYLENE LIGHT FOR AUTOMOBILES

By EUGENE BOURNONVILLE.\*

THE pure whiteness of the acetylene flame is closely akin to sunlight in the proportion of the various colored rays of the spectrum. It is evident from the table published by Munsterberg, that the light yielded by acetylene, not only more nearly approaches sunlight in the proportion of the rays of different wave length, but is even richer than sunlight in blue and violet rays, which are most essential to the chemical action of light. For this reason there is no other light which can compete advantageously with acetylene for the purpose of automobile lighting. It is evident that when a vehicle seldom travels at a speed less than ten miles per hour and most of the time much faster, no light is too good and the best light obtainable becomes a necessity to enable the driver of the traveling car to instantly distinguish all the obstacles which may be encountered. There are several different ways of producing acetylene light, which divide themselves into two principal classes: First, the making of gas by the use of a generator. Second, the use of gas under pressure, stored in properly constructed cylinders.

There are many ways of generating acetylene gas from calcium carbide, but the best method is that of dropping a small quantity of lump carbide at a time into a comparatively large volume of water. The carbide falls to the bottom where the gas is generated and travels upward to reach the surface of the water, cooling the gas and retaining most of its impurity by washing it. This system, however, cannot be used on automobiles, the apparatus required being too bulky. Accordingly it can be employed only for large installations, such as house lighting. Two water-feed types of acetylene gas generators are appropriate for auto use.

First: The one by which the water is above the carbide or is so arranged to have its level a few inches above it, permitting the water to fall on the carbide drop by drop, the flow of the water being regulated by a needle valve. This system has almost been abandoned for the reason that it is practically impossible to feed exactly the proper quantity of water to the carbide, so as to keep a constant and uniform flow of gas to the burner at the proper pressure. If the carbide is very rich or if the water drops too fast, gas will be generated in excess and will blow at the burner. If the water feeds too slowly or if the carbide is of poor quality from having been exposed to the action of the air, the gas will not generate fast enough and the result will be too little pressure for proper combustion, producing a dim yellow light which will smoke and very rapidly carbonize the burner.

The type of acetylene generator for automobile use and the one which is in almost universal use, is the one in which the water enters the carbide chamber at the bottom. The carbide chamber is an inner compartment located in a larger one which acts as a water reservoir and at the same time serves as a water jacket. The only connection between these two chambers is a small aperture in the bottom of the inner chamber. The moment that the valve leading to the chamber is opened, allowing the gas to pass out of the carbide chamber, the water takes its place and comes in contact with the carbide, thus generating more gas and by increasing the pressure in the carbide chamber forces the water out by the same aperture that it entered, but as the gas is gradually used, the water reenters the carbide chamber, thereby maintaining an even pressure. When the generator is not in use, the pressure keeps the water from contact with the carbide.

The only other method of using acetylene for automobile lighting is to have the gas compressed in special cylinders. Acetylene, or any other gas, in empty cylinders, can only be compressed about once the capacity of the cylinder for every atmosphere, say for every fifteen pounds of pressure. Accordingly, a cylinder of a capacity of one cubic foot at a pressure of 150 pounds, would only contain ten times its capacity, or ten cubic feet. This would

\*Formerly chief engineer of the Commercial Acetylene Company.

not be practical, as a cylinder would be entirely too bulky, and furthermore, compressing the gas in a cylinder without any means of checking the propagation of the explosive wave to the whole volume and contents, would render the system very dangerous in case of fire, and also for many other reasons. Acetylene being a highly endothermic gas, it is always advisable to protect it when compressed from any excessive external heating. An acetylene cylinder should never be installed next to the muffler or alongside of the exhaust pipe, as is very often the case.

This brings us to the storage of acetylene compressed in porous substances and dissolved in acetone. It is marvelous, the large quantity of acetylene which can be stored in a comparatively small receptacle at a pressure of 150 pounds, when the cylinder is constructed in accordance with the patents and methods of the Commercial Acetylene Company, controlling all the U. S. patents.

The cylinder is filled completely with a substance of very fine porosity and which, if compressed to a solid, would only fill 20 per cent. of the total volume of the cylinder; accordingly having a porosity of 80 per cent. This porous substance, in case of internal ignition caused by external heat or otherwise, is a safeguard against explosion as it will prevent the explosive wave from passing through the whole volume of compressed gas, but will localize the explosion without raising the pressure in the cylinder more than about 5 per cent., and consequently is considered not explosive when all other details of manufacture are observed, such as the entire absence of copper or its alloys, etc.

This porous material is saturated with acetone in the proportion of about 40 per cent. of the cubic contents of the cylinder. Acetone, which is a liquid, is a great solvent of acetylene gas and absorbs twenty-five times its own volume when at 62 degrees Fahrenheit, for every fifteen pounds pressure to which it is subjected by forcing acetylene gas into the cylinder with the aid of a gas compressor. For example, one quart of acetone at fifteen pounds pressure will absorb fifty quarts, and at 150 pounds pressure, it will absorb 250 quarts. When the pressure is released, the gas leaves the acetone in the same state that it entered.

When acetone is charged with acetylene gas at 150 pounds pressure, the liquid is non-explosive as has been demonstrated several times, a spark plug having been inserted into one side of the cylinder and set off without any explosion taking place or injuring the cylinder in any way, provided that the cylinder is properly constructed in accordance with the above described methods. According to my own personal observation and opinion, there are very few cylinders on the market which are properly constructed.

This for the following reasons. First: Some manufacturers are trying to get around the patents. Second: Some are trying to manufacture cylinders as cheaply as possible so as to compete with others by cutting prices and not by making their own product worth the price. Third: Cylinders manufactured by those not familiar with the chemistry of compressed gas and who do not realize the danger of neglecting the slightest details.

As to the most suitable size burner to be used for automobile lighting, numerous tests have thoroughly demonstrated the fact that a burner consuming 3-8 cubic foot of gas per hour will project all the light that a six-inch mirror reflector is capable of handling. If a 3-4-foot burner is used, the acetylene flame being opaque will retain the rays that are reflected by the mirror within the area of the flame, so that the rays thus reflected are lost as far as the illumination of the road is concerned. Accordingly, the ideal light is a concentrated one in as small a flame as possible so as not to obstruct the rays projected by the reflector, and the use of anything larger than a 3-8-foot burner not only produces practically no more light, but is simply waste. A white flame can only be obtained with pure gas, the loss from impurities being 15 to 20 per cent. of the luminosity.

**Again the Old Cars at the Old Stand in New York.** For the eighth time in the course of its existence the doors of Madison Square Garden were thrown open on Saturday last, and the manner in which the public responded to the invitation to view the same makes of American cars that they have flocked to visit for several years past appears to be ample refutation of the idea entertained in some quarters that the day of the show is already on the wane. This is the third occasion on which the Garden has been filled with exhibits of the same makers of cars, and the first on which the foreign element will be entirely lacking. Nothing radically new was to be looked for, nothing out of the way to be expected, yet the keen anticipation of the many who arrived in New York a few days previous in order to be able to take in both shows, and the manner in which they filled the Garden on the opening and subsequent nights, spoke volumes for the hold the automobile show has on the public as an institution of widespread and absorbing interest.

Lined up in imposing array in the Garden are the products of those makers who were more than the backbone of the American industry but a few years ago—who were the very industry itself, and who, even now, are responsible for a very substantial portion of the American annual output, both in number as well as in the value of the cars turned out. Familiar names, familiar faces, and familiar cars greet the visitor at every turn about the attractively decorated arena or its annexes.

It is safe to say that no one goes to a show nowadays expecting to find revolutionary designs, and confined as it is to the Selden interests, there cannot even be the expectation of seeing those new Western productions—that the independent show is responsible for—at the Garden, in view of which the attendance and the interest manifested on every hand tell a tale of their own, the moral of which would seem to be that the show is worth every dollar it costs in publicity gained. And there has seldom been as striking an illustration of this as the very successful show that is now filling every square foot of space in the Garden with American-made products.

**Does It Pay to "Knock" the Other Fellow's Car?**

Apart from those things that are absolutely reprehensible or downright dishonest, most of us are governed in our business relations and policies by a single guiding star. Does it pay? If it does not, we do not delay in following that sententious admonition of the vernacular to "forget it." If it does pay, we are apt to cling to a practice, the following of which has no other excuse for continued existence. The habit of what is known in the current slang of the day as "knocking" is something about which there is a difference of opinion when judged by the foregoing clear-cut standard. Some automobile dealers apparently regard the quickest and most effective way of selling their own cars is to belittle those of any the prospective customer may happen to mention. They combine not a desirable feature that the buyer is looking for, while his is an absolute paragon of all the virtues automobile.

The average man who buys an automobile gives the matter considerable thought before he invests. He is neither a child nor an idiot, nor, on the other hand, a technical expert. He does not implicitly believe every word the salesman tells him, as a boy might, nor does he permit himself to be gulled as if he were *non-compos*, nor can he give his informer the lie direct, because he is not familiar with automobile construction as a whole, or the good and bad points of the particular cars that the agent is at pains to condemn so roundly. No car is all good points, and few, indeed, are thoroughly bad, but even if they were, the agent is not a disinterested judge. Surely "knocking" forms no part of the art of salesmanship, for the man of common sense is far more apt to become disgusted with the prejudiced aspersions of the narrow-minded individual who is trying to sell him a car than to be decided in his choice of the latter by such petty and underhand means. The letter of a Western correspondent who appears to have suffered to the extent that he still has his money and none of them have sold him a car, shows that it does not pay, if evidence of that fact were needed.

**Has the "Horsepower Situation" Been Cleared?**

There has been more juggling with the term horsepower since the advent of the automobile than there had been prior to then from the time of Watts, and it does not seem as if the numerous attempts made to bring the matter of horsepower ratings down to the popular level were entirely successful. Abroad, the Royal Automobile Club, and here, the A. L. A. M., has tried its hand on the evolution of a standard. Theoretically, the latter is beautifully simple, but practically it hardly appears to work out in the manner in which even its formulators intended. Naturally it is intended for popular consumption, so to speak, and as such could not be expected to form more than an approximation, but it does not even do that. Loyalty to official standards is shown by the A. L. A. M. members and their salesmen in its adoption, but the rapidity with which the latter make haste to inform the inquirer that the real output of the motor is fully 50 to 60 per cent. greater reveals their belief in its accuracy. But apart from the fact that it tends to overrate small motors slightly, and underrate large ones grossly, the layman is as much confused by the fractional ratings as he was by the old-time hyphenated style.

## TWO-WHEELERS GIVE EVIDENCE OF POPULARITY

By W. F. BRADLEY.

**T**HOUGH in restricted quarters in the basement of the Garden, motorcycle enthusiasts display an enthusiasm which augurs well for the continuance of the two-wheeler, despite the growing encroachments of popular two-seated runabouts. Excepting that every maker has abandoned powerful heavy-weight machines in favor of a type of medium power and as light weight as possible consistent with strength, there is a wide diversity among the exhibits.

In frame design there are representatives of every school, the complete frame—that is a frame from which the entire motor might be removed without destroying the unity of the frame; the broken frame—the crankcase uniting the two stays; and the class of which the Indian is one of the best-known examples, in which the motor is combined as a part of the frame of the machine. Each class has its own supporters, its own merits and demerits, and it would

be impossible to single any machine as best merely because of these features.

Some type of shock absorber or cushion head is recognized as a necessity for every motorcycle, it being impossible without a device of this nature to travel at even a moderate speed without suffering from excessive vibration. Not only is a good cushion necessary, but the mechanical construction of the device should be of the best and give every guarantee of security. An interesting arrangement is found in the spring fork of the Thor, consisting of a one-piece stem and lower connection with triple keyed top connection. Four levers connect the fork stem of the frame with the parallel extending fork sides, making eight connecting points of ample size and all equipped with ball bearings. To obtain still easier riding the cushion fork of the Indian has been doubled, the change having been effected without in any way destroying the line of the machine. A strengthening of the spring forks forms one of the features of the new models of the R-S, the reinforcement consisting of a small tube passing from the eye in the fork end to the fore part of the crown. On the Styria common European practice is followed by a double front fork, without the use of any spring device. The Curtis has a somewhat similar construction, though a spring fork can be added at a small extra cost. A new spring fork has been de-

signed for the Marsh-Metz, consisting of a flat three-leaf spring held by three bolts under the fork crown; the springs act in either direction, doing away with any recoil arrangement.

Single-cylinder machines still comprise the majority of the exhibits; there are "twos"—a number of them—conspicuous being the Indian, the Marsh-Metz, and the Curtis; one "four" from the F. N. factory in Belgium, and an eight-cylinder racer, shown by the G. H. Curtis Company, conclude the departures from the small power classes. It is doubtful if all the single-cylinder machines can develop sufficient power to carry a rider over the more difficult parts of country roads, but the present tendency very wisely seems to be toward a medium power with lower weight and high efficiency.

Automatic intake valves are still in a majority, but that majority is not so great as was the case even a couple of years ago. The new model of the Indian, for instance, is now made with either mechanical or automatic intake valves. The mechanical arrangement is a single cam, operating the exhaust valve direct and the intake valve by means of an operating arm fastened to the exhaust valve lift, the intake valve still being placed in the cylinder head. The mechanical intake is certainly an improvement, and owing to its simplicity and ease with which it can be fitted, doubtless numbers of Indian users will consider it advisable to have their models fitted in this way.

With magnetos at their present price it is hardly to be expected that every motorcycle will be equipped with this source of electric current. Yet there are an increasing number of medium-priced machines which now have this improvement. The F. N. of Belgium four-cylinder machine, with superimposed valves, the intake being automatic, follows the best European practice with a high-tension Bosch magneto, inverted and carried on an extension at the forward end of the crankcase. On all the Indian models for 1908 the option of a high-tension magneto is given at an extra cost. A similar offer is made by the makers of the R-S.

Between shaft and bevel gear, single chain, and various types of belts, there is sufficient variety of drives to satisfy almost everybody. In a few cases there is an option on one machine of both gear and chain drive. This is so in the Indian, where on all models but the 3 1-2-horsepower single-cylinder machine, either gear or chain drive may be obtained. All gears are fully protected by a gear case, easily removable at will. An interesting type of drive is employed on the F. N. four-cylinder motorcycle, consisting of bevel gears and shaft, all completely encased. A flexible connection is provided by four helical springs in the flywheel, to take up any shock between engine and transmission.

CURTIS SWIFT AND POWERFUL EIGHT-CYLINDER RACER.

## PREPARING FOR FRANCE'S DECENNIAL SHOW

PARIS, Nov. 1.—In twelve days President Fallieres, surrounded by members of the Government, and escorted by Republican Guards, will pronounce the stereotyped discourse marking the invasion of the public through the front gates of the Grand Palais and the escape of an army of workmen from the rear of the building. It is one of the peculiarities of the Paris Salon that each year the big hall shall be in an impossible state of chaos two hours before the opening, and that everything shall appear in perfect shape when the Republican trumpet is blown. Having been so during the past nine years, there is every reason to believe that the tenth show, crude as it is to-day, will have every piece of brasswork polished and every lamp in position when Baron Zuylen and his helpmates stand with bared head awaiting the arrival of the President.

It has always been the design of the Automobile Club of France that their annual Salon should be in every sense a national affair. What little opposition has sprung up from time to time has been promptly suppressed and the one national show organized more on the lines of a world's fair than a trade exhibit. Although the Grand Palais in the Champs Elysées is retained, it has long been too small to contain all those clamoring for admittance. Thanks to a complaisant municipality, almost the entire Esplanade des Invalides, a huge plot of land separated from the Palais by the Alexandre III. bridge, has been placed at the disposition of the club at a rental which would appear reasonable for a Harlem flat. Three main roads had to be closed, but the diversion of vehicular traffic has never been a serious matter when the interests of the Salon were in question.

On the Esplanade des Invalides a metal and wood hall, with an area of about 36,000 square yards, equal to the total of the Grand Palais, has been erected for commercial vehicles, machinery and motor boats. Every provision is here made for exhibiting machinery in motion, all machine tool makers and constructors of stationary power plants having made arrangements for showing their products under working conditions. Judging from the shafting in position, some of the stands will contain a dozen heavy machine tools under power.

### City Streets and Squares Comprised in Decorative Scheme.

Gustave Rives, the wizard of the show, has announced that the decorations for the decennial exhibition will be a big advance on those of previous years. It is difficult to understand where improvement will be made, for last year every electric power plant in the city was called upon to render aid. Yet Rives has taken charge of the two big halls, the Avenue Alexandre III., the Bridge, the Champs Elysées, and the Place de la Concorde, with the intention of clothing them in a luminous robe which will beggar even the gorgeous dress of the Russo-France fête days.

Certainly the Paris exhibition will hold its own as the largest and most gorgeous of the world's automobile shows, but it is certain to be affected somewhat by the London show opening one day earlier and closing at the end of seven days. London does not claim to have more than an excellent trade show, realizing that it is impossible to rival Paris in size, decorations, illuminations and national éclat. But the commercial side of the British exhibition has been carefully developed, and as all Continental firms must, in view of their foreign trade, exhibit in London, and British exhibits and visitors are few at Paris, John Bull believes that he has obtained commercial supremacy. The Paris show remaining open two weeks longer than the London one, there will be an opportunity for English visitors to attend both, but few will make the journey for business purposes only.

It has been customary during the holding of the Paris Salon to unite automobilists in conference on subjects of universal interest, large conference halls being set apart for this purpose within the Grand Palais. Although three subjects have been

chosen this year, alcohol, touring, and motor boats, only the discussion on alcohol is likely to create international interest. Judging from the list of scientists, technicians and statesmen at the head of the different sections, the alcohol conference will be one of the most important ever held in connection with Paris Salons. Interest is more than local, among the many distinguished foreigners having intimated their intention of being present being Frank Rutter of the United States Department of Agriculture. The four technical groups will deal with the application of alcohol to the automobile, its application to other than the automobile industry, heating and lighting, and technical matters connected with the production, denaturation and carburetion of alcohol. The economic section, also divided into four classes will discuss production, application, legislation and customs, and the use of alcohol for army transport service.

At the touring conference the conditions discussed will be those of France, foreign conditions only being involved in so far as custom and police regulations affect the home tourist. There is a desire to obtain uniform automobile laws and regulations for Europe, but it is certainly too early for any practical move to be made in this direction. During the show a meeting of club officials will be held, as in previous years, to draw up the base of an automobile calendar for the coming season. As some representative of almost every automobile club in Europe is present during the Salon, it is possible, by mutual agreement, to outline a program the events of which will not clash, and by means of which manufacturers are advised in ample time of coming events.

### What New Features May Be Expected at the Salon.

Although French constructors are never anxious to give advance information of their models, and this year is no exception, mechanical features at the coming show will doubtless be more numerous than in 1906. The commercial automobile, from light delivery vehicles to Renard trains, will form a strong class. It is realized that the field for powerful high-priced touring cars has been overdone, the overproduction in this direction being almost entirely responsible for the evil reports which have gone into circulation during the past two months. Commercial vehicles will this year occupy a space almost as large as that devoted to powerful touring cars, the progress made in this section being enormous. A still newer development is the small two-seated runabout, with either a two-cylinder or a single-cylinder engine, selling for about \$500. For the most part these small cars are built by firms formed by men who have broken away from the big factories; indeed, there are not more than two firms of international repute engaged in this line. Darracq, among the big makers, is now ready with a couple of cheap runabouts, one with a single cylinder and the other with a two-cylinder engine. A large number of big factories promise a complete touring car at prices ranging from \$1,200 to \$1,500.

Contrary to certain reports, the use of side chains will not be extended. Indeed, indications are that the contrary will be the case, every firm in France now adopting shaft drive for its smaller models. Panhard and Dietrich, both of whom have persistently stuck to the chain, announce shaft drive for their lighter cars. More town vehicles and more taximeter cabs than ever before will be a feature of the show. There is a strong tendency, especially in the smaller town vehicles, to cast all four cylinders in one block. Six cylinders will be in evidence, but will certainly not be one of the features of the show. Important speed tests this year, which have much less connection with fashion than automobile shows, have failed to develop any remarkable features in the "six" that is not already possessed by the "four." Leading French makers, important among them being Renault, will produce six-cylinder models generally as a concession to a popular fad, and not because of any firm belief in their superiority.

# WHY THE SIX-CYLINDER MEETS ALL REQUIREMENTS

By ALEXANDER WINTON.

**A** MAKER of four-cylinder cars, who is also making a few sixes, has appeared in the daily and trade press with the declaration that sixes are inferior to fours, by which admission he confesses that he is now making inferior cars—in other words, that he is retrograding. However, he explains his fall from grace by stating that he was “forced into it,” and since the force must have come from without, we can only conclude that it represented competition and public demand. He does not successfully show why the public should demand inferior cars and still be willing to pay more for them than it pays for fours.

He rightly states that one claim in favor of the six is that it runs smoother and easier than the four, adding that the torque is said to be “much more continuous.” Continuous is not a comparative term. Either a thing is continuous or it is not continuous; there is no half-way continuity. “Continuous” describes that which is absolutely without pause or break. Torque means driving pressure exerted on crank shaft and driving shaft. The only element in an automobile that exerts driving pressure is the motor, and whether the driving pressure is continuous or not depends wholly upon the number of pistons.

## Performs Same Operation.

Note the operation of a single-cylinder motor, because each individual cylinder of an automobile motor (four-cycle) performs the same operations, whether there be one, four or six cylinders in the motor unit.

In the single cylinder there are four piston strokes to each complete cycle, each cycle requiring two complete revolutions of the crankshaft, as follows:

1. First half revolution of crankshaft. Gas drawn into the cylinder. Termed the suction stroke.
2. Second half revolution of the crankshaft. Gas compressed in the cylinder. Termed the compression stroke.
3. Third half revolution of the crankshaft. Combustion and expansion of gas in the cylinder. Termed the power stroke.
4. Fourth half revolution of the crankshaft. Burned gas expelled from the cylinder. Termed the exhaust stroke.

Note also the demonstrated and accepted mechanical fact that the power of the power stroke does not continue throughout the entire stroke. Hence in a one-cylinder motor power is exerted less than one-fourth the time.

## Always One Stroke Behind.

In the four-cylinder motor, the four pistons are so timed in relation to the crankshaft revolution that each piston is at all times one stroke behind its predecessor. So, while one cylinder is developing power, another is compressing, another drawing in a charge and another exhausting. Thus power strokes in the various cylinders follow one another. Power impulses, however, are not continuous. They are separated by intervals of no power at the end of each power stroke, for, as already stated, power is exerted during only part of the power stroke. On this point there is no difference of opinion among mechanical engineers.

Due to this condition, it follows that the power stream of the four is not continuous, but intermittent, and that the torque of the four is never continuous, but always intermittent, and this condition is not changed no matter how fast the four motor may turn over.

Notwithstanding this truth, the four-cylinder spokesman declares that:

“It is probably not out of place to state that we claim to obtain in our four-cylinder motor the gradual and even application of torque that is talked so much about in the six. This we accomplish by means of a superior carbureter, which we have developed after ten years of constant experimenting to get a perfect gas-making apparatus.”

Any remarks relative to carbureters in relation to torque are as irrelevant as a claim of perpetual motion. The best car-

bureter in the world cannot cause a piston to be driven farther than the length of its stroke. “Argument” cannot disregard established mechanical laws.

## Each Has Done Its Work.

In the six-cylinder, as in the four, two crankshaft revolutions complete the cycle, and during this period each of the six pistons has performed its four strokes. The pistons of the six are timed in relation to the crankshaft revolution so that each cylinder is not one complete stroke behind its predecessor, as in the four, but is only two-thirds of a stroke behind its predecessor. Thus in the six, the power of one power stroke is not spent before the succeeding power stroke takes hold. Consequently, the power stream of the six is never intermittent, but always continuous, and continuous means “absolutely without pause or break.” Recall also that torque means driving pressure exerted on crankshaft and driving shaft. Torque cannot be continuous if power is not continuous. Continuous torque in the four is a physical impossibility. In the six torque is ever present and cannot be prevented, no matter how slowly the motor may turn over.

## Smoother Running; Easier Riding.

And continuous torque means smoother running and easier riding than is possible with intermittent torque; also it means longer life to car and lower fuel consumption.

The four-cylinder spokesman says:

“The basic argument in favor of the six-cylinder is the continuous torque—but let us carefully dissect this argument for a moment. A six-cylinder motor geared, say, two to one, delivers twelve impulses to the rear axle for every revolution of the wheels. Acting on precisely the same principle, a single-cylinder motor geared twelve to one will also deliver twelve impulses to the axle for every revolution, and the forward movement of the car is just as smooth as though six cylinders were employed.”

A six-cylinder motor geared 2 to 1 delivers six, not twelve, impulses in the period stated, and a single-cylinder geared twelve to one delivers six, not twelve impulses. This mistake on the spokesman's part is one of mathematics, an exact science. Does it increase his authority on points that may be somewhat more speculative?

The comparison of a single cylinder with a six can hardly be serious, however, for with both motors giving the same number of revolutions per minute the single would drag along one mile, while the six would cover six miles. And in doing that work the piston of the single cylinder would travel six times as far as any one piston of the six, hence being subjected to six times the wear and tear.

And beyond all that, the torque of the single cylinder can no more approach the continuity of six-cylinder torque than can two parallel lines meet. For continuous torque is obtained only from power strokes that overlap, as they do in the six.

“It has been claimed,” declares the spokesman, “that six cylinders of given size will develop 50 per cent. more power than four cylinders of equal dimensions, all other things being equal. But is this really the case? I think not. Years of experimenting have shown us that with all other things equal the addition of two more cylinders does not produce 50 per cent. more power. In fact, a much smaller percentage than that was all that could be noticed after over a year of expert testing.”

This is the prize avowal.

One horsepower is that volume of energy capable of raising 550 pounds through one foot of space in one second of time. If one cylinder of given size will develop 10 horsepower—that is, be able to raise 5,500 pounds through one foot of space in one second of time—no influence on earth can prevent two exactly similar cylinders from developing twice that power. And on the same reasoning, if four of these cylinders develop 40 horsepower, it would be a freak of mechanics if two additional

cylinders exactly similar (working under identical conditions) did not develop 50 per cent. more power. This is not a matter of individual opinion or of expert testing; it is the working out of mechanical laws.

#### A Pertinent Question.

Perhaps the four-cylinder spokesman contends that of four exactly similar cylinders, total rating 40 horsepower, one cylinder would develop 15 horsepower, another 13, another 7, and another 5. If so, which of the four is the 15-horsepower cylinder, and why? Again:

"The principal difficulties with the six-cylinder, which no one can deny, are that it requires 50 per cent. more mechanical parts, 50 per cent. more ignition apparatus, 50 per cent. more gas apparatus, has 50 per cent. more valves to grind, has 50 per cent. more weight, and requires 50 per cent. more radiating surface than a four-cylinder motor of equal power, and consequently requires 50 per cent. more care and 50 per cent. more repair bills."

This statement is loose. For instance, mechanics know that radiating surface increases as the square, whereas cylinder volume (horsepower) increases as the cube. The statement of radiating surface is therefore inaccurate and tends to discredit the other statements. "Fifty per cent. more ignition apparatus" might be taken to mean that if four cylinders require one magneto, six would require one and a half magnetos, and we assure an innocent and unsuspecting public that this fear has no foundation in fact. Read this:

"It is somewhat questionable whether the double complication resulting from the added two cylinders is warranted by the improvement in regularity of running and freedom from vibration secured."

This quotation is not from the four-cylinder spokesman's remarks. It is the serious talk of an American automobile authority, Albert L. Clough. One might think he were arguing against six cylinders, but he isn't. His talk was delivered two years ago, and he was arguing against the four and in favor of the two-cylinder, which to-day has as few friends to defend its cause as the four will have one year hence. The quotation is introduced merely to show that the old stock arguments, which no longer hold good against the four, are now being tried in vain against the six.

"Fifty per cent. more care and 50 per cent. more repair bills," says the spokesman.

Let us see. Does the four require 100 per cent. more care than the two? Are its repair expenses 100 per cent. greater? If not, then the relative argument against the six also fails.

#### Laments the Length.

The four-cylinder spokesman laments the length of the six-bonnet and wheelbase. On the Winton Six-Teen-Six the bonnet is seven inches longer and the wheelbase is but eight inches longer than on the four-cylinder Model M.

"The carburetion difficulties increase because there are two cylinders taking in gas at the same time, and great care must be used to distribute this evenly to all cylinders."

The answer is in the carbureter manifold; this can be properly made so that the difficulty is overcome. Ought to be an easy task for the maker who can produce torque by means of a carbureter.

On the Winton Six-Teen-Six the carbureter manifold is unique and efficient, so efficient in fact that no carburetion difficulty has been encountered. And in six-cylinder construction generally, since suction through the carbureter is continuous, carburetion reaches a perfection unknown where suction is intermittent, as in four-cylinder motors.

"Think," says the four-cylinder spokesman, "of an ordinary chauffeur attempting to grind in twelve valves and to time a double system of ignition, or to adjust the valve timing!"

Mercy! The man who can grind in one valve can grind in a thousand with no greater mental exertion per valve. The man who can time one system of ignition can time a dozen. And the man who can time one valve can time a limitless number of them, because an increased number of cylinders and valves does not change the relation of a single valve to its particular piston.

"Throughout the world," he declares, "it is almost invariably the case that racing machines are four-cylinders."

The most wonderful racing performance the world has ever seen—1,581 miles in twenty-four hours—was done by a six-cylinder car. And that performance hardly bespeaks carburetion or ignition difficulties either.

"We ourselves build six-cylinder cars," he adds, "to give the speed and power that a few drivers demand."

Excessive speed and power are the least important advantage of the six. The more important, due to overlapped power strokes and continuous torque, is that the six requires actually less developed power to do driving work. Take two cars of equal rated total horsepower, and the six-motor will drive its car at a slower motor speed than the four. And, accordingly, the six always has in reserve over normal work a supply of power not possible in the four. The six has a wider range of speed on high gear than has the four, requires less gear changing, is sweeter running, has less wear and tear, gets the more power out of gasoline and is more silent than the four. These, not excessive speed and power, are six strong points.

"Why, then," concludes the four-cylinder spokesman, "is it necessary to use six cylinders if the torque of the four is practically constant, the supply of gas being even and steady at all speeds?"

It wouldn't be. The fact is that these are the identical points on which all fours, irrespective of make, fall down, due not to individual shortcomings of the four-cycle principle. And these faults are overcome in the six.

## 6 MOTOR TRUCKS CAN DO WORK OF 15 HORSE-DRAWN VEHICLES

INDIANAPOLIS, IND., Nov. 6.—Probably the most interesting change from horse-drawn vehicles to motor trucks that has ever been made in Indianapolis has just been effected by the City Express Parcel Delivery Company. This company has just installed six gasoline 1 1/2-ton trucks to take the place of fifteen delivery wagons and twenty-two horses.

The company operates a parcel delivery service almost exclusively, although some general transfer work is done. Such service, of course, requires that a large number of small packages be delivered as quickly as possible, the tariff on each package being small. Thoroughly satisfactory service has not been obtained with horses because it required too much time to deliver a few packages. Tests have shown that six motor trucks can do the work of fifteen horse-drawn wagons without much difficulty.

Instead of training its old drivers for truck service, the company has found it more practical to employ experienced chauffeurs

at \$15 a week and place a second man on each truck for deliveries. The trucks are kept in a public garage at \$20 each per month, under a maintenance contract. This guarantees that should a truck break down en route another will be sent at once to take its place. The saving over horse-drawn wagons is estimated at \$300 per month.

#### DIAMOND RE-ELECTS OLD OFFICERS.

AKRON, O., Nov. 4.—The annual meeting of the Diamond Rubber Company resulted in the re-election of the old board of directors and officers. The directors are: F. A. Hardy, A. H. Marks, W. B. Miller, A. H. Noah, O. C. Barber and E. K. Hardy, Akron; R. G. Lake, Chicago. The officers elected are: President, F. A. Hardy; vice-president and superintendent, A. H. Marks; secretary, W. B. Miller; treasurer, A. H. Noah.

## NO RADICAL CHANGE IS TO BE EXPECTED IN THE FUTURE

By HAYDEN EAMES, M.E.

FROM the viewpoint of the engineer the gasoline automobile of the present day does not differ radically from a type that was accepted as standard about three years ago. In the electric field, both for pleasure and commercial vehicles, the problems as far as engineers were concerned were settled about three years ago. The problems that confront manufacturers to-day are those of an educational nature, to teach the users, particularly in the commercial field, to operate their cars economically. During the past few years the automobile has passed through a crisis. Some few have failed, but the majority of the manufacturers of high-class cars have accepted a type which I do not believe will differ materially in ten years from that of the present time.

The day of "exclusive features," commonly referred to as talking points, has passed, and this is entirely logical. The automobile of to-day does not depend on sensationalism to sell, either in freak construction or price. The industry has passed through the experimental stage years ago. The typical design which has proved itself by time, and as only time can prove it, has been adopted. The evolution has been slow, but each year's experience has added valuable lessons.

Gottlieb Daimler, a name known everywhere in technical circles, gave the initial impulse to a now great industry by developing the modern four-cycle internal combustion motor from a purely experimental to an entirely practical basis. This, then, was the starting point, and it will surprise many people to learn that this was as far back as 1835. The laws that went into effect at the time that automobiles first made their appearance were so stringent and absurd that they, perhaps more than any other thing, arrested the development of the automobile. Even in 1900, the few leading manufacturers had little in common, and the cars differed radically both in design and in engineering principles. There were all types and kinds of engines, transmissions and

drives, but in 1903 and 1904 engineers began to learn from experience and to apply these principles.

The four-cycle, four-cylinder motor, sliding-gear transmission, and, in fact, some of the foreign cars at that time were built on sound engineering principles and from which the car of 1908 has deviated but little. One point that has taken a long time to determine is the question of shaft or chain drive. The best engineers at one time unanimously agreed on the chain drive. The question was not a question of material, as sometimes stated, nor was it a question of weight, but everyone realized that until the floating type of axle was invented the shaft drive was far from right. It might stand up a year, perhaps more, perhaps less, but ultimately it was sure to go.

For this reason the best engineers clung to the chain drive, not because it was mechanically right, but because it was better and more reliable than anything yet introduced. With the advent of the floating type of axle, the weight taken off the shafts, the question of alternate stresses was eliminated and the problem to be solved was simplified to producing a shaft strong enough for the twisting or torsion of driving. This floating type of axle solved the problems of drives and the best cars are using it exclusively. The chain drive was adopted principally because it worked. On some of the earlier models anything was adopted that worked. The fundamental principle of constructions had not been decided upon, and refinements were given little attention.

The automobile shows of this year do not show anything radically different from the shows of 1905. A few of the manufacturers have apparently thrown aside the hard lessons learned through years of experimenting and branched off on entirely new tracks which are not based either on sound engineering or good business judgment, but in this respect the automobile business differs little from the manufacture of any standard article.

## FROM THE STANDPOINT OF THE IMPORTER OF FOREIGN CARS

By CLINTON R. MABLEY, IMPORTERS' AUTOMOBILE SALON.

AN industry is built up by the demands of human beings, no two of which are apt to agree on exactly the best method of accomplishing a result or the best result when accomplished. The consequence is that progress is demanding more strongly every day the recognition of a compromise brought about in one of two ways: either by allowing one branch to supply the needs of a people who prefer the products of that branch, and the other to supply the demand which favors its product; or, by assimilation, in which the best of each branch is eventually combined for the superior product at the highest price, and the remainder resolved into a combined product of a lower grade, which also fills an ever-increasing demand. Undoubtedly either one of those two processes will eventually apply in the solution of the American-*vs.*-foreign-automobile question, as they are fundamental principles applicable to any industry.

I might mention as an indication in favor of the former the increasing confidence in the American mechanical world, in foreign engineers and producers. Hitherto, Americans were loath to admit that there were any engineers or mechanical brains anywhere in the world worthy to compete with them. We may thank the imported automobile as an enlightener and educator in this respect. In addition to the great body of American automobile buyers, we have a very enlightened class of purchasers to-day who realize the value of the workmanship and selected materials of the foreign car and prefer it.

So we have continual converts to the foreign car in principle and practice, and we also have an increasing number of converts to the lower price, and all that it represents of American manufacture. The advantage in the proportion of the business is

undoubtedly with the merchant who sells at the lower prices always, on account of the original lower investment, and on account of the more numerous replacements. This condition calls for the purchase by one individual of a greater number of units in a given number of years than in the case of the foreign car, where the purchaser looks more to the permanency of his greater first investment, and naturally expects to handle fewer units in the same length of time. As an argument for assimilation, we have the daily increasing number of foreign car makers selecting and using good points of American design, and some particular desirable material pertinent to America, and the recognition of the necessity and desirability of meeting American conditions generally.

So we have the peculiar spectacle of foreign cars with American road clearance, tread, wheelbase, and American bodies, and American cars with a foreign design of chassis, German design of transmission, French and German-made coils, magnetos, springs, axles, frames, and even whole motors, castings, and a widespread recognition of foreign workmanship in many of the most important parts of the automobile.

Negotiations have been opened recently by the German military authorities and the Wright Brothers, of Dayton, O., for the sale of their flying machine. Hart O. Berg, of Philadelphia, the financial backer of the Wrights, has been favorably received by the military authorities and negotiations have been entered into which are not likely to terminate soon on account of the numerous technical difficulties. The Wrights withdrew their proposition to the French Government before visiting Berlin.

## AUTOMOBILE NOTES FROM EUROPEAN CENTERS

THE international motor show at Copenhagen closed on October 8, after having been visited by about 50,000 persons, a very good percentage for the capital. Among these were the King, who, although one of the few monarchs not enthusiastic on the sport, could not but countenance an exhibition of such industrial importance. He was accompanied by his brother, the King of Greece, and as they both examined all of the exhibits most carefully, paying quite a lengthy visit to the Ford stand, it is to be hoped that motoring in Denmark, until now a sadly-treated step-child of legislation, will take a more upward curve. Business was satisfactory on the whole.

A London news agency has excited German circles by stating that the Emperor intends visiting Brooklands during his stay in England and that Mr. Edge will hold a race on the track at the time of the Imperial inspection. The Emperor has received a well-known South German king of commerce in private audience, who laid the project of a motor road from Frankfort to Berlin before the monarch. No further details of the interview have been made public as yet.

Switzerland, long notorious for its anti-motoring tendency, is weighing a proposal to prohibit motor traffic of any kind over Swiss roads on Sunday, in order to let the population use roads, lanes and by-ways freely and to its heart's content without being disturbed by the national bugbear. And this in a country which has to count on its influx of visitors for a large share of its existence.

The money-bearing propensity of motor-car taxation is once again most clearly testified to by the income derived by the Flemish province of Brabant from this source. Each horsepower here is charged at 10 francs, that is to say, if there are five cars with 25-horsepower each, that means that 125 horsepower are taxable. All in all, Brabant possesses 1,021 cars, with a total horsepower of 14,694, which, multiplied by ten, throws an annual sum of 146,940 francs into the coffers of the province.

The chauffeur of the Queen-Dowager of Italy, Cavaliere Utoe Carolate, is at the same time a very clever doctor and combines both these qualities in the royal trips, which are the most frequent of any royalties. Her Majesty was in Germany in October and drove back to Italy in her car as well, her favorite and almost only mode of locomotion now.

Intending tourists through Austria will hear with satisfaction that the Austrian A. C. proposes to erect signboards bearing the different international signs throughout the Empire next year. Sub-committees have been formed, who report to a head committee in Vienna.

King Edward VII. and the Prince of Wales have accepted invitations to be official patrons of the Olympia Show, London, which opens November 11 and continues until the 23d.

A motor fire brigade train will make its appearance in Nuremberg early next year, where the city fathers have set aside 25,000 marks for the preliminary outlay.

## FOR AMERICAN AUTOISTS LANDING IN ITALY

IN view of the fact that large numbers of autos are now being shipped from New York to Naples for touring purposes, Vice-Consul H. M. Byington submits the following information regarding the Italian customs regulations at Naples:

The entire charge of the custom-house agents and expenses on week days is 80 to 150 lire (\$15.44 to \$28.95) and on Sundays and Government holidays from 150 to 300 lire (\$28.95 to \$57.90). In order to clear a motor on Sundays or holidays, it is necessary to arrange on the preceding day, so as to insure the presence of the special officials. The duties payable are as follows: On cars weighing up to 500 kilos (1,125 pounds), 200 lire (\$38.60); from 500 to 1,000 kilos (1,125 to 2,250 pounds), 400 lire (\$77.20); over 1,000 kilos (2,250 pounds), 600 lire (\$115.80). These duties cover the accessories of the motor.

Owners of motor cars on a visit to Italy can deposit the amount of the duty on entering the country, to be reimbursed to them on leaving, either by sea or by land. The reimbursement of the deposit cannot be effected after six months have elapsed, and to meet such a case application must be made to the Treasury Department of the Government for the necessary extension.

The Touring Club of Italy has a special arrangement with the Treasury Department which will save owners of motor cars much trouble and inconvenience. On demand of a member of a foreign touring club and on the deposit of the maximum sum of 600 lire the Italian Touring Club will issue a special certificate to be presented to the customs authorities on entering the country. On leaving the country the certificate must be duly indorsed to that effect, and the Italian Touring Club will at once refund the amount deposited on delivery of their certificate with indorsements.

For every motor car entering Italy the following documents must be exhibited to the customs: (a) Papers giving the name and address of the owner. (b) Certificate of the chauffeur showing that he is entitled to drive a car and the number and make of the car. The charge for landing a motor car is 25 lire (\$4.83), irrespective of its size. Accessories cannot be admitted without payment of duty in cases where the car enters the country on deposit for temporary importation. Motor cars which have been introduced into the country on the deposit arrangement are free from Italian taxes until expiration of the six months or such time as extended by the Government.

## WHAT THE AUTOMOBILE IS DOING FOR CENTRAL ASIA

CONSUL-GENERAL G. B. Ravndal, of Beirut, referring to Prince Borghese's feat as leading contestant in the Peking-Paris automobile race, which was started from the Chinese capital June 10, and concluded some fifty-eight days later on the arrival of Prince Scipione Borghese in Paris, quotes the following from the *Times* of India:

The car's achievement will give enormous impetus to emigration and colonization of the Asiatic wastes. The automobile is destined to be the pioneer of unknown lands, and when, through its agency, development of the country has reached a certain point, the railway will follow, binding new districts to the rest of the world.

Mr. Ravndal adds: In this connection, I call attention to my previous report on "Reclamation of Mesopotamia," of which the following is an extract:

The question of carrying tourists to Palmyra in automobiles, starting at Homs, has been seriously discussed in Beirut and Damascus, and one is led to believe in the possibility of a regular freight service between Damascus or Aleppo and Bagdad by automobile transport wagons. Experiments in the Sudan and Congo Free State have proved their feasibility. In the plains of Syria, Mesopotamia, and Arabia, oil-motor freight cars would seem to have a future. Petroleum is comparatively cheap, owing to the proximity of the Caucasian oil fields.

## AN AUTO'S CLIMB OF A ROADLESS CALIFORNIA MOUNTAIN

SAN FRANCISCO, Nov. 1.—On a recent October morning the squirrels and lizards on the summit of Mt. Diablo were startled to hear the rumble of wheels and the hiss of escaping steam. Up the hillside, slowly but surely, came a great mechanical monster, until, with one last whistling tug, the White steamer was on top! Mt. Diablo, situated in Contra Costa county, is the gauging point from which all surveys are taken, having an elevation of 3,810 feet.

The difficult ascent was accomplished by William M. Gardiner, Pacific Coast agent of the White Company, and William L. Slimmon, Claude A. McGee, Ross B. Main, and Alexander Beyfuss. Mr. Gardiner was at the wheel and the story is most interestingly told in his own words:

"We left San Francisco Saturday afternoon, spending the night at Danville, a little town about three miles from the foot of the mountain. At five minutes past 7 o'clock Sunday morning we left the hotel, and, stopping at the Boyd ranch, asked for permission from the manager of the Oakwood stock farm to use their road. He willingly granted our request, laughing in his sleeve at

WHITE STEAM CAR ON THE SUMMIT OF MT. DIABLO.

us, for he had no idea that we could make use of the permission and get to the top of the big hill.

"There are seven miles of unbroken grade from Oakwood farm to the summit, absolutely without a level spot. With regard to the road, it may safely be said that there was very little to be found. Overgrown in some places by dense underbrush, washed away in other places by the heavy rains of the winter, after which it had been baked by the scorching sun of summer, and everywhere covered with dust and loose stones, some parts were so washed away as to leave but two feet of road, the other side having been dug out by the winter torrents. Three years ago, the Sierra Club, on one of their long tramps, climbed this hill, and it is said that their provision wagons are the last to have used this road.

"We used the Diamond flat tread tires in order to get the greatest amount of traction possible, but even then the wheels skidded, and we were, in many places, compelled to jump along, or rush over the space, so that the momentum would keep the car from overturning or dashing down the cliff. Several times we were compelled to abandon what had been the road and strike off to one side, into the underbrush, which was so dense as to

make it necessary for us to cut it away. Even then, we were compelled to remove our side lamps, and our car was pretty badly scratched up. One bridge we crossed looked so very weak that even after a close investigation of the under-pinning timbers we did not linger any in getting over it.

"We arrived at the summit of Mt. Diablo at 9:25, making the record time of 2 hours 20 minutes. Of course some of this time was spent in opening gates, investigation of roads and bridges, planning detours over cattle trails, and taking photographs. We did not try to make time up the mountain, merely wishing to attain our object, that of reaching the top; but I am convinced that we could again negotiate it in one hour.

"Descending the hill was an excitingly dangerous proposition. We were obliged to hold tight and be hurled helter-skelter down the rough road, hearing the reverberations of the stones, dislodged by our wheels, as they struck the bed of the canyon, several hundred feet below. We just had to keep going, it being impossible to slow up enough to snatch a photograph. I think we were all relieved when we reached the foot of the hill without having been precipitated into some canyon. None of us are particularly anxious to again make the trip. It is enough that we have chiseled on the State monument, way up among the clouds, the words: 'White Steamer, the First Car to Reach this Eminence.'"

### SOCIAL FUNCTIONS OF THE SHOWS.

"It's always fair weather when good fellows flock together," is the motto of the Fairweather Club, which, on the evening of October 30, held its first monthly dinner at Reisenweber's, with General John Tyler Cutting the guest of honor, and L. C. Humphreys as the toastmaster of the occasion. Over a hundred participated, including many out-of-town tradesmen visiting the show. General Cutting heard many things said in his favor and few to his detriment. Creswell MacLaughlin, editor of *The Schoolmaster*; Henry Duncan, William Perrett, and John C. Wetmore were the star performers in the oratorical line.

#### A Rehearsal of the Telharmonic Idea.

At Telharmonic Hall, Thirty-ninth street and Broadway, Friday noon, Madison Square Garden show officials and press men were given a partial rehearsal of the Garden musical program, to be supplied by the wonderful instrument which transmits music to all parts of the city. The principles of telharmony were explained and an inspection made of the entire plant, which contains 145 dynamos, generating as many kinds of electrical currents, these currents when in predetermined combination making the tone the musicians release to the absent audiences. A buffet luncheon was a part of the function, of which A. H. Chadbourne, well known in automobiling, was the energetic factor.

#### Flat Tires Entertain Press Visitors.

The Flat Tire Club gave its banquet to the out-of-town newspaper men at the Hotel Cadillac, Friday evening, November 1, prominent tradesmen from various parts of the country being included among those invited to buy their own tickets. The affair was capably conducted by an executive committee consisting of E. E. Schwarzkopf, Henry Caldwell, Duncan Curry, Fred J. Wagner and H. T. Clinton. In the dressing of the banquet hall much originality was shown. Flat tires formed a part of the decorations, lamps helped to illuminate, and Toastmaster Caldwell utilized a horn in his characteristic filling of the rôle of chief fun-maker. There was all sorts of speechmaking and the occasion served to bring together many leaders, both automobile trade and press.

The press agents of automobiling have a dinner scheduled for to-night, and 'tis said that no undertakers will be tolerated in the heart-to-heart spread.

## INDIANA'S PROPOSED AUTOWAY.

INDIANAPOLIS, IND., Nov. 4.—It is the cherished plan of Indiana automobile owners, and also of a number of county commissioners, that within a few months there will be a speedway stretching from Indianapolis to Chicago, for the exclusive use of automobiles. Such, at least, is the hope of Indianapolis car owners, which has been given much encouragement by John McGregor, a commissioner of Marion county, who now has the plan in charge. Because of his influence throughout the State, it is believed that he will meet with much success in broaching the plan to commissioners in counties north of Marion.

It develops that at a recent State convention of county commissioners, held in this city several weeks ago, that the matter was suggested by Mr. McGregor to a number of commissioners and that he met with much encouragement. It was pointed out that a roadway set aside by law for automobiles exclusively would lend safety to travel and permit slightly greater speed, if desired.

Mr. McGregor proposes a road from Indianapolis northward to South Bend and then to Chicago by way of Laporte. This would take in Noblesville, Tipton, Kokomo, Logansport, or Peru, Rochester, and Plymouth, as might be decided on later.

There has been much opposition to automobiles by farmers in northern Indiana, who have objected to automobiles using the same highways used by horse-drawn vehicles. It is believed that these same farmers would welcome a plan to take automobiles off of the leading north and south roads between Indianapolis and Chicago. In speaking of the proposed highway, Commissioner McGregor said:

"The building of a road for exclusive use of automobiles would not entail heavy expense to any county through which it would pass. In a few years it would almost pay for itself in damage suits saved, which now result from automobiles, buggies and heavy wagons using the same roads. It would also be a great accommodation to automobile owners and would do much to lessen the hatred of unfriendly farmers for automobiles."

It is probable that Marion county will take the first step toward such a highway in the spring.

## SHOULD HELP INDIANA ROAD BUILDING.

INDIANAPOLIS, IND., Nov. 6.—The Indiana Railroad Commission last week made a ruling that will be of great benefit to road building when it fixed a maximum rate for hauling road building materials. The rates become effective within thirty days and highway improvements that have been held up because of the almost prohibitive rates for hauling materials will be taken up and pushed to completion.

Although Indiana has exceeded all previous records for road building this year in counties where material is scarce, it has been almost impossible to carry on improvements because of high railroad rates.

Last June the commission directed inquiries to each board of county commissioners in the State and replies were received from fifty-three out of ninety-one counties. It appeared from these responses that at that time no less than 898 miles of new roads were under way and that in fourteen counties road materials had been exhausted. It was found also that in twenty-four counties high rates had retarded work and that about 700,000 tons of materials are needed in the State for improvements and repairs each year.

The rates as arranged by the commission are based on mileage in cents per net ton, fixes a minimum car load at 40,000 pounds and provides for both a local and joint rate. The rates range from 24 cents per ton, local rate, and 28 1-2 cents per ton, joint rate, for a ten-mile haul or under, to 81 cents local and joint per ton for a haul of 225 to 250 miles.

About thirty-five railroads doing business in Indiana are affected by the decision.

## P. S. C. BLOCKS ROAD IMPROVEMENT.

NEWARK, N. J., Nov. 4.—Improvement of the plank road, which forms the chief travel route between New York and Newark, and as such the autoist's gateway to Philadelphia, Atlantic City, and other cities lying in that direction, has long formed a project close to the hearts of Jersey automobilists, as well as of vast importance to the commercial interests of this part of the State. As a matter of fact, it is one of the most traveled highways in the East where autoists are concerned, and, by the same token, is in the worst state of disrepair, being absolutely dangerous for night travel.

Many attempts have been made to have the old plank construction over the meadows replaced by modern highway construction, but all to no purpose, and it is the opinion of Joseph H. Wood, formerly president of the New Jersey Automobile and Motor Club, publicly expressed in a letter, that the Public Service Corporation is responsible for blocking the improvement. This corporation controls most of the street railways in the State, and its lines monopolize one-fifth of the plank road, but according to the Hudson County supervisor of roads the concern is unwilling to bear its portion of the expense of repair or maintenance. In the meantime the appropriation made by the Legislature several years ago for this purpose cannot be utilized owing to the attitude of this corporation.

The New Jersey Automobile and Motor Club has taken the matter up, but thus far the committee appointed for the purpose has had to rely upon its own efforts, coupled with those of local commercial interests, as no information could be obtained from the boards of freeholders in either Essex or Hudson counties regarding the reason for not utilizing the above-mentioned appropriation. The club has taken up the matter in earnest and will exert every effort to call public attention to the matter and in other ways compel the proper authorities to take action.

## EN ROUTE TO LAKE MAHOPAC, WATCH OUT.

Editor THE AUTOMOBILE:

It may interest some of your readers to know that the trap at Merritt's Corners, on the road to Lake Mahopac, N. Y., is now in operation on the double curve at Echo Lake. I was arrested Saturday, and charged with covering the distance laid off at the rate of ten miles per hour, the rate allowed being four miles, although only about half the distance is on a curve, the rest being on a straight road, which should increase the average speed allowed. The judge, Ogden S. Bradley, of Ossining, would not accept jewelry as bail, so I had to pay the fine. He denied that any case had been tried as stated in "The Automobile" of October 17, so I have sent him a copy of the article, though it will probably only tickle the "judge" to see his picture in print. ROBERT N. BAVIER.

New Rochelle, N. Y.

WILLIAM JENNINGS BRYAN UTILIZES A "45" PREMIER.

Having several appointments recently to lecture in various sections of Greater New York and vicinity, and these having been scheduled at close intervals, it was determined by William Jennings Bryan that the automobile would be the most desirable mode of conveyance. The committee selected the new 6-cylinder "45" Premier to enable the distinguished statesman to meet his appointments.

FRANKLIN CAR MAKING ITS RECORD OF 49 SECONDS IN THE CLIMB OF DUGWAY HILL, NEAR ROCHESTER, N. Y., ON OCTOBER 19.

## WHAT THE A. A. A. LEGISLATIVE BOARD IS DOING

A CONVENTION of members of the American Automobile Association interested in legislation was held during the Grand Central Palace show. The meeting was called to order by President W. H. Hotchkiss, and discussions and deliberations turned over to Charles Thaddeus Terry, chairman of the Legislative Board. In his address on the subject, Mr. Terry, among other things, spoke as follows:

The Legislative Board of the American Automobile Association has kept in touch with the legislative situations in the various States to whose legislatures statutes relating to automobiles or the use of the highways were presented at their last session. While the general trend of legislation, as gathered from the data collected by the chairman of the committee, seems to be in the direction of reasonableness and a somewhat larger degree of fairness than heretofore and to show somewhat of abatement of the unreasoning hostility to the automobile and its use, because of their novelty, it is to be regretted that automobile legislation is even yet of so diverse and divergent a nature throughout the several States as to indicate an imperative demand for one of two things, to wit., either the speedy enactment of a Federal law covering the field as far as may be, or the enactment throughout the States of a uniform automobile State law framed upon the model of the best of the present State laws, with improvements thereon if possible.

The best of the energies of the Legislative Board, while sometimes diverted by other work which properly comes within the scope of its duties, has been directed to the preparation of the best bills possible within its capacity and the efforts to secure their passage.

From the outset, the plan to secure a Federal enactment of the kind described has met with universal favor, and the bill pre-

pared and introduced in Congress at its last session has met with practically no adverse criticism, although copies of the proposed bill were widely distributed before it was introduced in Congress and suggestions and criticisms invited.

With regard to the proposed uniform State motor vehicle act, the task was as heavy as in the case of the Federal bill, if not more so, because the Board has met with the problem of attempting to harmonize in the proposed bill the various sentiments of various States with reference to legislative provisions in this regard, and to reach for the various States a common ground which might be defended on common sense principles as adequate for the protection of the public and the preservation of the rights of automobilists alike.

The energies of the Legislative Board will be directed toward the enactment of these two bills during the coming winter. In preparation for the campaign in behalf of the Federal bill, literature in the form of letters, of which there will always be a large supply on hand at the offices of the association, has been prepared, to be distributed by the automobile clubs and their members throughout the country and by individual automobilists not connected with any club, not only among other automobilists but among all classes of citizens, using them to communicate directly with their congressmen in support of the bill and to secure the favorable action of the committee and of Congress upon the measure. These letters have been prepared and await only the signature of any one who is sufficiently interested in the subject to use whatever influence may be at his command to secure the passage of this bill without the necessity of his expending any more time or effort than may be involved in the signing and mailing of such letters, unless he be willing to render the still more effective service of writing his own personal letters and sending them to members of Congress, particularly in his own district, and inducing his friends to do the same.

### NEW YORK'S \$10 FINE RULING REVERSED.

Instead of being able to escape with a fine of \$10, regardless of the enormity of the offense or the status of the driver as a persistent violator of the law, under Justice Truax's decision handed down last August, which held that the ordinance of the Board of Aldermen had superseded the State law, offenders in the metropolitan district are now liable to spend a term in jail instead, as the decision in question has just been reversed by the Appellate Division of the Supreme Court. Justice Truax's ruling was rendered in the case of William Hainer, who was arrested and held for trial in Special Sessions, but who was released on a writ of habeas corpus. The case was appealed by the District Attorney, who is now sustained, so that the State law will again take effect as formerly. The latter imposes a fine not exceeding \$100 for the first offense, and of not less than \$50 nor more than

\$100, or imprisonment not exceeding thirty days, or both, for the second offense. This law was drawn up by President William H. Hotchkiss and Charles T. Terry, chairman of the Legislative Board of the American Automobile Association, and the ruling of the Appellate Division meets with their approval, as well as of other prominent autoists.

### THAT FAULTY PENNSYLVANIA LAW.

PHILADELPHIA, Nov. 4.—After to-morrow any chauffeur who cannot produce a municipal license when called upon will feel the heavy hand of the law. A recent regulation of City Councils—which, by the way, has nothing to do with the State license—requires motor vehicle operators here to secure a license from the city's Bureau of Steam Boiler Inspection. Already upwards of a thousand permits have been issued.

HOW LICENSED MAGNATES UTILIZED THE UNLICENSED CARS.

### UNLICENSED RIDE OF THE LICENSED.

In order, on Friday last, to reach the private rehearsal of telharmonic music, one of the features of the Madison Square Garden show, the members of the show committee, through a mix-up in arrangements, found it convenient to utilize Rambler cars to ride from the A. L. A. M. offices, in East Forty-second street, to Telharmonic Hall, on Broadway, near Thirty-ninth street. It so happened that Rambler cars were available in the emergency, and E. H. Cutler, George H. Day, S. T. Davis, F. L. Smith, W. E. Metzger, and Marcus I. Brock appeared on Broadway in the product of the Thomas B. Jeffery Company, which not only declines to become a part of the licensed body, but also keeps aloof from the independent association. Apparently there must have been some kind of a conspiracy in the proceedings, for a photographer was on the job, as is made apparent by the accompanying picture.

### A NEW "SCORE" FOR THE MAXWELL.

That a matter of twenty youngsters can be accommodated in an automobile was demonstrated recently by Frank J. Griffin, of New York City. Mr. Griffin has several daughters attending school at the Morristown convent, at Morristown, N. J., and recently stopped at that institution with his 1905 model 16-20-horsepower Maxwell touring car. As a score of the youngsters clambered aboard the auto there was nothing to do but give them a ride, and the manner in which such a number managed to stow themselves about the car in one fashion or another in order to participate in the impromptu outing would be a revelation to the body builder who was proud to say its capacity was five passengers. It scarcely needs to be added that the bevy of future misses had the time of their lives while the fun lasted.

TWENTY LITTLE LADIES WHO ENJOYED A MAXWELL RIDE.

### ADDING TO THE LIFE OF AN AUTOMOBILE.

"Much could be added to the life of an automobile and to the satisfaction that it gives to its owners," says J. D. Maxwell, of the Maxwell-Briscoe Motor Company, "if people would bestow upon the automobile but a part of the attention they give to other property. Take, for instance, the item of winter storage. Few people who store their cars for the winter think of taking the trouble to put the car on horses and to remove the tires from the wheels. The insides of the rims, too, should be cleaned and a coat of enamel applied to the inner surfaces where the tire rests. This will prevent corrosion and will leave the rim smooth. A good idea also is to give all polished brass surfaces a coating of heavy oil, slab oil, for instance. A tube of ordinary gum grease, likewise, will preserve the lamps, the radiator, steering post, and other parts that would be injured through corrosion. The top should be opened and cleaned with oiled waste, to keep it smooth and flexible. Of course, these rules find but little application in this section of the country, since we have a rather open winter which permits the use of the automobile practically all the year."

### SIGNS ASSIST MUCH IN TOURING.

Much progress in the work of marking the motor highways with Rambler road signs is reported by Thomas B. Jeffery & Company. Twenty-five hundred signs have already been placed

PLACING THE ROAD SIGNS ON THE WISCONSIN ROADS.

by men sent out from the Rambler factory at Kenosha and from the Rambler branches. Twenty-five hundred additional signs are ready to be shipped to Rambler agents for immediate placing. The first lot of signs was used principally in the Middle West. Many were put up between Milwaukee and Chicago. The signs are of sheet steel, durable and can be seen from a distance.

### CHICAGO-NEW YORK RECORD HOLDER DEAD.

HARTFORD, CONN., Oct. 28.—After partially recovering from an attack of pleurisy, Burt Holcomb, a former holder of the New York automobile record, died at Southern Pines, N. C., as the result of a general breakdown. Burton Beckwith Holcomb was born in Hartford in 1870; after working some time with the New England Railroad Company, he began testing cars of the Electric Vehicle Company, and four years ago drove a Columbia car from Chicago to New York in seventy hours. Later he lowered the record to 56:38. The interment took place at Hartford.

Woodland, Cal.—The new garage of Van Zee & Bielar, which was opened in one of the Martinelli stores, on Main street, early last summer, has had a most prosperous season. The concern is the local representative of the makers of the Buick cars, and have equipped their establishment in an up-to-date manner throughout.

## LATE AUTUMN DOINGS OF THE AUTO CLUBS

### SWAIN WINS BRAZIER CUP WITH "JACK RABBIT."

PHILADELPHIA, Nov. 4.—"Unofficial returns" would seem to indicate the election of Charles J. Swain (Apperson "Jack Rabbit") as next year's holder of the Brazier cup, emblematic of victory in the annual cross-country run of the Automobile Club of Philadelphia, held last Saturday in a driving rain-storm. The reason for the delay in announcing the standing of the eight contestants—the rest were evidently scared off by the ominous front put up by J. Pluvius—is that Mr. Swain failed to follow the route indicated by the official program by using Walnut street instead of Locust street to reach the finish. It may be that he will be additionally penalized, and the order of finish changed.

The conditions of the contest were that the 88.6 miles were to be covered in 5 hours 19 1-2 minutes—neither more nor less—to secure a perfect score. This time represented the maximum in which the course could be covered with due regard to the State, municipal, borough, and village speed ordinances in force. Of course, the contestants were ignorant of this official limit.

Penalties were incurred for being ahead of, as well as for being behind the schedule, and although all the contestants suffered the infliction of demerits, the officials wisely refrained from announcing whether they were imposed for overpunctuality or tardiness. According to the time dope, there should not have been an arrival at the club's quarters at 1409 Walnut street until 1:20 P.M.—the first car started at 8 A.M. sharp—yet at that hour the majority of the contestants were lined up along the curb waiting to officially finish and get in out of the drenching downpour. Here it is reasonable to presume that the penalties inflicted were in most cases for something other than late arrival at checking stations and at the finish. These checking stations were located in three unknown points out in the country, and contestants were penalized for failure to pass them "on the dot." Hence the following "unofficial" list of penalties imposed would seem to be moderate to a degree: Charles J. Swain (Apperson "Jack Rabbit"), 14 1-2; Allan Wood 3d (Ford), 15 1-2; E. L. Miller (Packard), 17; H. P. Bailey (Winton), 18 1-2; C. Yarnall Abbott (Pennsylvania), 23; Dr. W. A. Phreaner (Winton), 23 1-2; Herbert Morris (Stoddard-Dayton), 31 1-2; G. B. Fletcher (Packard), 35 1-2.

The main points on the course were West Chester, Phoenixville, and Norristown, and the roads were selected with a view of giving the contestants a little of all kinds and an object lesson in picking routes to avoid toll-gates.

### CHICAGO CLUB EXPECTS THIRTY ENTRIES.

CHICAGO, Nov. 4.—Eleven entries are in hand for the 600-mile three-day reliability run of the Chicago Motor Club, November 26, 27 and 28, reports received from the scouts who went to New York raising the number from three, where it reposed for several days. Harry P. Branstetter was the man who made the "killing," and he yesterday wired Chairman Root of the contest committee that he had received two Dragon and one Wayne entries and that he had received positive assurances that the Pennsylvania, American, Overland, and Marion would forward entries the early part of this week. Eleven others are regarded as good as being in. Counting no chickens as hatched, the contest committee sees at least fifty-two cars. Letters received by Chairman Root show that the makers regard the rules as almost ideal.

### LONG ISLANDERS' ANNUAL FALL REUNION.

BROOKLYN, N. Y., Nov. 4.—The entertainment committee of the Long Island Automobile Club announces that the annual fall reunion of the club will take place at the clubhouse on Friday evening, November 8. An excellent bill of advanced vaudeville will be rendered, after which refreshments will be served.

### WORCESTER PREPARING FOR ANNUAL BANQUET.

WORCESTER, MASS., Nov. 4.—Thursday evening, November 14, is the day set for the annual banquet of the Worcester Automobile Club, which will be held in the hall connected with the Front street clubrooms. The board of governors is arranging to have the after-dinner speaking assume the form of a symposium of methods of transportation or travel. There will be seven forms of the subject treated by the speakers—airial travel by one, automobiling by another, and to which Frederick H. Elliott, secretary of the A. A. A., has been asked to respond; steam and electric railways will each have something said for them, the horse will have its innings, so will the bicycle, and there will be suitable consideration for those who, either from preference or necessity, are pedestrians. Last year's banquet was enlivened by clever parodies written by the club's attorney, D. M. Pardee, and there will be some more of them this year.

### BERKSHIRE AUTOMOBILE ASSOCIATION FORMED.

PITTSFIELD, MASS., Nov. 4.—Monday, October 28, witnessed the formation of a new club in this city—the Berkshire Automobile Association—with the following board of officers: President, Daniel England; first vice-president, Franklin Weston; second vice-president, Samuel G. Colt; treasurer, R. P. Parker; secretary, S. H. Clapp. The lines on which the club is formed are unique, inasmuch as it will look after the protection of the automobilist and the individual citizen as well in the use of the highways.

As the Berkshires are so tremendously popular with automobilists it will prove welcome news that there is a business organization in this vicinity which will consider it a duty to post highways, unsafe roads, grades, etc., and generally protect and post the transient in his use of the Berkshire roads.

### C. A. C. ANNUAL MEETING NOVEMBER 14.

CHICAGO, Nov. 4.—Members of the Chicago Automobile Club will assemble in general meeting for the first time in their new clubhouse, November 14, which is the occasion of the annual meeting and election. The administration ticket as presented by the nominating committee is as follows: For president, Ira M. Cobe; first vice-president, Frank H. Peitsch; second vice-president, T. J. Hyman; secretary, N. H. Van Sicklen; treasurer, Charles E. Gregory; directors, John Farson, Claude Seymour, Walden W. Shaw, T. N. Koehler, A. J. Banta and F. D. Countess.

Several changes in the constitution and by-laws will be given consideration, among which will be a proposition to increase the non-resident membership limit from 100 to 250, and another to extend the resident membership limit. The projected merger of the Chicago Automobile Club and the Chicago Motor Club will also be considered.

### A. C. OF MARYLAND ELECTS ITS OFFICERS.

BALTIMORE, Nov. 4.—The annual election of officers of the Automobile Club of Maryland took place recently in their clubrooms, and resulted as follows: President, James Stone; vice-president, Dr. H. F. Rowe; secretary, E. A. Dolle; treasurer, Ernest J. Knabe; board of governors, C. M. Dowe, M. S. Hess, F. W. Coale, F. W. Darling, Roland Morton, and O. Y. Yellott. Following the election of officers a collation was served.

The Automobile Club of Maryland and the Automobile Dealers' Association of Baltimore have announced that the Baltimore show will be held November 16 to 23, in the show building at Maryland and Mount Royal avenues—the scene of the first and most successful show ever held in this city. The exhibition is being arranged by B. B. Johnston, the original promoter, who thoroughly understands the managing of a show.

### AERO TROPHY TO GERMAN PILOT.

At a special meeting of the Aero Club of America, last Monday evening, President Cortlandt Field Bishop officially presented the James Gordon Bennett aeronautical cup to Oscar Erbsloeh, pilot of the balloon *Pommern*. According to the deed of gift, the cup will be held by the German Club until the next competition to be held in Germany during 1908.

At the meeting it was announced that the distance covered by the *Pommern*, according to official measurements, was 871.74 miles; Alfred Leblanc and E. W. Mix, who manned the *Isle de France*, were declared to have covered 866.59 miles. The world's long-distance record of 1,196 miles, established in October, 1900, by Comte de la Vaulx, in a trip from Paris to Russia, remains untouched, but the pilots of the *Isle de France* have succeeded in breaking the time record, 41 hours 5 minutes being a record stay in the air. In commemoration of this splendid performance Mr. Bishop declared that he would present a special medal to the French Club. Other awards announced were \$2,500 to Oscar Erbsloeh, given by the donor of the cup; \$1,000, given to Leblanc by the citizens of St. Louis; \$750, to Baron von Abercron; \$500, to J. C. McCoy; and \$250, to Alan R. Hawley.

### GLIDDEN MAKES AERIAL TOUR.

Having qualified as a sky pilot under the most skilled foreign experts, Charles J. Glidden made his first balloon trip in this country last Tuesday, accompanied by Leo Stevens of New York. The ascent was made at Pittsfield, Mass., at 10:45 A.M., and a successful landing made at North Springfield, Vt., at 2:18 in the afternoon. The distance covered was about 140 miles, though on an air line the distance between the two points is only 85 miles. To escape a storm just after they had crossed the Massachusetts line, the balloon had to be sent above the clouds until it reached an altitude of 8,500 feet.

### ATWATER-KENT TEST IN PROGRESS AT GARDEN.

With its A. C. A. seal still unbroken, the Atwater-Kent spark generator, which was officially started by Albert W. Jacobi of the A. C. A. show committee on the opening of the Palace show on October 24, is still being run at the Garden. A test is being made of the mileage obtainable from a set of dry cells, and for this purpose an Atwater-Kent spark generator is enclosed in a glass case together with a Jones speedometer-odometer, four spark plugs and six Columbia dry cells. An electric motor furnishes the power to run the apparatus at a rate corresponding to a speed of 25 miles an hour on the road. At the close of the Palace show the odometer recorded 1,700 miles and in the two-day interval between the shows the outfit was kept running at the salesrooms of Harry Houpt, the New York Thomas agent. The reason for the extraordinary mileage obtainable with dry cells in connection with the Atwater-Kent apparatus is due to the fact that the spark generator makes but one spark for each explosion, and this is produced by what may be termed an instantaneous make-and-break contact in the primary, thus minimizing the current consumption, as the contact lasts little, if any, longer than the single contact of the ordinary coil trembler when in action.

### LOCATION OF HARRIS OIL CO. EXHIBIT.

An error in the October 31 issue of THE AUTOMOBILE gave the space of the A. W. Harris Oil Company as No. 256 Balcony, and it is located in No. 256 Basement. Therefore, those who seek this company's lubricants must go below and not aloft.

**Laramie, Wyo.**—During the past summer Laramie's most ambitious auto establishment has been erected for Elmer Lovejoy and C. W. Brandis at 414-416 Second street. It is a one-story building with basement, floor of concrete with brick sidewalls, and front of iron and glass.

### INDESTRUCTIBLE STEEL WHEELS.

Representing the most advanced creation of the metallurgist's art, combined with the highest engineering talent in metal-working, it seems anomalous that the running gear of the automobile should still continue to be made of the same material that characterized the most primitive attempts at wheel-building—wood. Wherever lightness, combined with the maximum of resisting power, has been a desirable feature, wood has almost invariably had to make way for its modern successor—high-grade steel—and in view of the amazing results forthcoming from the scientific handling of this material in automobile construction, it seems odd, to say the least, that its use has not been extended to the art of wheel-making much earlier.

The Indestructible Steel Wheel Company of Chicago, Ill., has been making a wheel of this kind for some time past, aptly named "Indestructible," but the chief objection to its use on pleasure cars has been that of appearance, as the two parts of the wheel were made of stampings in the shape of disks, reinforced by conventional spoke-shaped bosses, which made it resemble a solid wheel, making a car look heavy. This has been overcome in the new pleasure car model, now being exhibited at the Gar-

AN INDESTRUCTIBLE STEEL WHEELER THAT MADE LONG TOUR.

President Fish and Vice-President Metzel of the Indestructible Steel Wheel Company, of Chicago, in their Premier Roadster, in which they have just completed a tour of Indiana, Ohio, and Michigan.

den and demonstrated on a car outside, by making an open pattern, the disks being perforated between each pair of spokes. This gives it an appearance of lightness more in accord with its actual weight, as the wheel is transparent and resembles the ordinary type when in motion, thus overcoming the only objection to it, and its adoption on American cars as a part of their standard equipment is already under way.

### LOCO HAS TWO CHASSIS, EIGHT TYPES.

Although the Locomobile Company of America produces eight different models in all, in touring, runabout, limousine and landaulet types, there are but two distinct chassis, a 20-horsepower, known as Type E, and a 40-horsepower, designated Type I. Owing to a mistake in copying, Type I, illustrated in our issue of October 31, was described as 20-horsepower. This was incorrect, the rating of this model, according to the A. L. A. M. formula, being 40 horsepower.

### ALFRED REEVES SAILS FOR EUROPE.

Alfred Reeves, general manager of the A. M. C. M. A., accompanied by Howard C. Marmon, of the Nordyke & Marmon Company, sailed Tuesday on the Kronprinz Wilhelm for Europe. A large party gave the pair a royal send-off, and Mr. Reeves was the recipient of a gold watch fob. He makes the trip in the interests of his association and will visit the London, Paris and Berlin shows, being gone in all about six weeks.

## BRIEF ITEMS OF NEWS AND TRADE MISCELLANY

Announcement is made that *The Power Wagon* will hereafter be published in Chicago, with offices in the Metropolitan block. Heretofore the paper has been published in Cleveland.

A handbook of "Hints and Helps on the Operation of the Motor Car" has been issued by the National Carbon Company, Cleveland, O. Ignition troubles are more especially dealt with, and there are a number of hints on the most common mechanical difficulties.

The New York Automobile Trade Association has been advised by the general freight agent of the Hudson steamship line that in the future gasoline motor trucks will be allowed on its piers. This adds one more to the list of transportation lines that realizes the importance of a rapidly-growing industry.

The Schubert Bros. Gear Company, of Oneida, N. Y., is contemplating the formation of large stock company for taking up the manufacture of automobile bodies on an extensive scale. The company, which at the present time employs upwards of one hundred hands, has been very successful in the manufacture of special racing bodies.

In connection with the third annual Automobile and Sportsmen's Exhibition, to be held in Montreal, Que., for one week, April 4-11, the management has entered into an arrangement with the Automobile Club of Canada whereby the show will receive the hearty co-operation of the club. Judging from the large number of applications already received, there is no question but what the show will in every way surpass its predecessors.

Five hundred dollars has been appropriated by the Minneapolis Automobile Club to help the city in paving University avenue, the street which connects St. Paul with Minneapolis. Only one mile of pavement remains to be placed to connect the two cities. The city finds itself unable to appropriate the sum necessary, and the automobile owners have put their shoulder to the wheel, with the result that all travelers on a much used highway will reap the benefit.

Every autoist who has used cuss words because of having to take out different licenses in different States, should lend his support to the congressional bill prepared by the American Automobile Association requiring uniform laws for motor vehicles in all States. The first step toward lending support to the bill is for those who are not members of A. A. A. to join the national body. Information about the law and other matters of the organization may be had from Secretary F. H. Elliott, 437 Fifth avenue, New York.

Philip S. Flinn, Arthur Banker, Rob McCurdy. Mr. Austin and three others drove No. 14, the four-cylinder Great Arrow of Mr. Flinn, from Pittsburg to New York in twenty-two hours' running time. The party came to attend the show, and will return in the car. The trip over was rough, for the roads were very bad as compared to their condition at the time of the A. A. A. Tour, when they were reviled by all. The trip was made without incident. The hood was not lifted throughout the trip and the tires were not touched. The car, which seven people occupied in all, has been driven 15,800 miles, and runs perfectly to-day.

In years past most of the imported and other highest-priced cars have been sold in New York and other big cities of the East, but according to recent experience the western cities are increasing their patronage of the highest class of cars remarkably. James Joyce, general manager of the American Locomotive Automobile Company, which has had a show of its Berliet cars in the Waldorf-Astoria for two weeks, says that the number from the West who are taking an interest in high-priced cars, and are willing to pay for them, is astonishing. He says that the visitors from a hundred miles beyond New York made light of all panic talk, and seemed prepared to indulge themselves in the best things to be had, even more freely than usual.

### RECENT BUSINESS CHANGES.

Announcement is made that the Rainier Motor Car Company will remove its headquarters in New York City on January 1 from its present location, Broadway and Fiftieth street, to the big corner building at Broadway and Fifty-sixth street, now occupied by the Hol-Tan Company. In the new building the Rainier company will be able to conduct under one roof the business which is now distributed in three buildings. The new quarters contain more than 43,000 square feet of floor space, is five stories high and has a basement.

### NEW AGENCIES ESTABLISHED.

M. J. Wolff, proprietor of the Williamsburgh Auto and Storage Company, 159-161 Clymer street, Brooklyn, N. Y., has taken the agency for the Matheson in that borough.

The Henshaw Motor Car Company, of Boston, has been appointed Eastern Massachusetts representative of the Olds Motor Works, and will handle the Oldsmobile exclusively with the Columbus electric. Associated with Manager Henshaw will be A. E. Adams, who has been connected with the Olds Motor Works for a long period.

The Empire Automobile Tire Company, of Trenton, N. J., has opened a branch house in New York City on Seventy-third street, at the juncture of Broadway and Amsterdam avenue, in the building formerly occupied by the Aerocar Company. The branch is under the management of Marcus Allen, who was for several years manager of the Auto Equipment Company, of Detroit. He is a New Yorker, however, and well known in the trade of the metropolitan district. A complete stock of Empire clincher tires and tire accessories has been installed.

### NEW AGENCIES FOR YORK.

YORK, PA., Nov. 4.—James A. Kline, general manager, and H. R. Averill, sales manager of the York Motor Car Company, upon their return from the Grand Central Palace automobile show, announced the new agencies for the Pullman cars. They are: F. E. Randall Company, Boston; Grout Gasoline Car Company, Providence, R. I.; J. P. Sullivan Company, New London, Conn.; Star Motor Car Company, Newark, N. J.; N. A. Barnett & Company, Cranford, N. J.; E. Gibson Company, Indianapolis, Ind.; Thomas & Tolman Auto Co., Washington, D. C.; Allenbyrg Auto Company, Spokane, Wash.; Hernandez Au-

tomobile Company, Havana, Cuba; Automobile and Marine Motor Company, Charleston, S. C.

With an order of 100 taximeter cabs, the local firm is considering the advisability of building them. This will necessitate an increase of the factory force and plant.

### PERSONAL TRADE MENTION.

H. T. Whittlesey, formerly of John R. Keim Company, of Buffalo, N. Y., is now with A. O. Smith Company, Milwaukee, Wis., traveling in their interests.

Warren T. Walker, formerly with the G & J Tire Company, is now connected with the Locomobile Company as general New England sales representative.

E. A. Sontag, formerly of the Frederick Sontag Company, of Boston, has associated himself with the Empire State Motor Company, of Houston, Tex., as manager.

A. M. Archer, American representative of Hotchkiss et Cie in the United States, sailed, October 31, on the *Baltic* for a four weeks' visit to England and France. He was accompanied by Mrs. Archer.

H. G. Martin, formerly with the Harburg Tire Company, has recently joined the forces of the Republic Rubber Company, of Youngstown, O., and will represent that firm in Brooklyn and Long Island.

C. G. Stowe, formerly New England representative for Speare's oils, has resigned and accepted a similar position with the Columbia Lubricants Company, of New York, which company will open a branch in Boston on or about January 1.

Oscar Warner has severed his connection with Wyckoff, Church & Partridge, of New York City. He has not announced his future connection in the industry, but it is understood he will be prominently identified with one of the large manufacturers.

W. J. Lamb has been appointed manager of the New York branch of the Fisk Rubber Company, at 1725 Broadway. Mr. Fisk has been an exponent of Fisk tires for the past six or seven years in and about Detroit, where he was manager of the local branch house.

Col. Charles Arthur Carlisle, purchasing agent for the Studebaker Automobile Company, of South Bend, Ind., has completed a very enjoyable trip with his family, in his Studebaker "30" car, through New York State, Connecticut, Massachusetts, Vermont, and New Hampshire.

E. W. Heddington has been appointed manager of the New York branch of the Haynes Automobile Company, to succeed C. B. Warren, who has been appointed sales manager for the company, with headquarters at the factory at Kokomo, Ind. Mr. Heddington has been associated with the New York branch for two years, the past year as Mr. Warren's assistant.

The Firestone Tire and Rubber Company, of Akron, O., has transferred J. V. Mowe to its Chicago branch, where he will look after the sale of the Firestone tires in the Chicago territory in the future. Mr. Mowe has been connected with the Philadelphia branch of the Firestone company during the past year. E. M. Eldridge, of Seattle, Wash., has joined the selling forces of the Firestone in New York City.

# The Safest Way to Store Gasoline

The NATIONAL is the only pump that discharges gasoline at every movement of the crank; it saves one-half the labor and one-half the time to pump gasoline; there is no evaporation or leakage; the tank is buried underground; the pump may be put in the building in a convenient place. It is the safest way because it meets all of the requirements of The National Board of Fire Underwriters.

For a Garage owner the National portable wheel tank will enable you to fill a car quickly by pushing the wheel tank by hand to the car. It is easily handled even in case the car would be at the curb.

The NATIONAL is also adapted to private motorists, also for lubricating oil storage. Ask for catalogue—it will explain all about the National System.

## The National Oil Pump and Tank Co., Dayton, O.

# THE AUTOMOBILE

VOL. XVII

NEW YORK—THURSDAY, NOVEMBER 14, 1907—CHICAGO

No. 20

## ON LAND AND WATER WITH CANOT-VOITURE

THREE hoots from a passing tugboat greeted the appearance of the *Waterland* in the calm waters of the Hudson last Tuesday afternoon. Whether they were notes of defiance or a shrill cry of welcome is impossible for a landsman to say, but certainly the recipient was worthy of an official welcome, and the skipper of the tug had his weather-eye open when from mid-stream he discovered in the small craft on the edge of the water something more important than usual.

The launching of the *Waterland* really took place on Broadway, opposite the Oldsmobile store, where for an hour a crowd

A Frenchman from Paris, M. Ravillier, conceived the idea of an automobile which would be equally at home on water as on land. He constructed his *canot-voiture*—one is at a loss whether to call it a craft or a machine—succeeded in interesting the army and the navy, and in selling the foreign patents to George E. Crater, who promptly shipped the boat, inventor, and the entire crew of one man to New York for demonstration purposes.

Externally the production has all the appearances of a motor-boat deprived of its screw and mounted on steel wheels. A front axle lodges in a space provided for it in the fore-end of

FIRST PLUNGE INTO AMERICAN WATERS OF THE FRENCH AMPHIBIOUS AUTO "WATERLAND," INVENTOR AND PILOT ON BOARD.

of sightseers had gathered around the boat on wheels, and had exhausted all its imaginative powers in an effort to discover its object in life. When the small boy hanging on the rear had been cuffed until he was glad to fall off, the blue-painted *Waterland* swung her bow round and scurried up Broadway, followed by a string of official cars and as many chauffeurs as happened to be passing and had half an hour to spare. Arriving at Fort Washington Park, the land and water production wormed her way down to the water's edge, halted an instant until her propeller case had been removed, then plunged into the stream under her own power, and bobbed in acknowledgment of the tug's salute.

the boat, and suspension is provided by a couple of semi-elliptic springs attached to brackets from the side of the craft. In the same way the rear wheels are suspended, drive being by means of side chains from a countershaft projecting through each quarter to a sprocket on each rear wheel.

Within the boat is a two-cylinder De Dion motor developing about 15 horsepower, which will drive the screw in regulation fashion, or will communicate power to the road wheels merely by a change of gear through a side lever. Shifting from either land or water drive is performed in the same way as an automobilist drops from fourth to third speed. Steering is by the ordi-

READY FOR THE RUN FROM BROADWAY TO THE RIVER.

nary method of an inclined column surmounted by a wheel, with the addition that the front wheels and the rudder are operated simultaneously whether on land or water.

Pressed steel is employed for the hull, this type of construction having been adopted, according to the inventor, to fit the boat for military service. In the French government tests the craft was made into a target with results visible to anyone caring to examine the paint work. With three passengers on board *Waterland* had but a small amount of freeboard, and although assurance was given that she could not capsize, none of the passengers asked for a demonstration or cared to inquire as to what would happen if a wave came aboard.

A dozen times in succession the boat came back to land, came completely out of the water under its own power, took a fresh consignment of passengers, then backed into stream again. The arrangement of the gears allowed either the road wheels and propeller to be used together or independently; thus, although the ground was so soft that the solid tired wheels sank almost immediately, the craft was able to come in and out without any external aid, notwithstanding the soft ground.

When everybody had been given an opportunity of testing the nautical ability of the *Waterland*, her Gallic crew ran her completely ashore and the spectators stood round in anticipation of a hill-climbing contest through unmacadamized Fort Washington Park. Instead of speeding up the engine, though, the crew took off the forward hatch and fitted a small capstan on the forecastle. A tow rope was flung overboard, one end attached to a tree, the other wrapped round the capstan in nautical manner, and the De Dion's two cylinders induced to develop power. From a pulley on the forward end of the crankshaft a belt communicated with a countershaft, transmitting movement to the

COMING ASHORE—NO OUTSIDE HELP NEEDED.

capstan through bevel gears. A loose and a fixed pulley, and an ordinary belt shifter allowed the capstan to be either operated or remain idle. With this arrangement the steep, rough hill was climbed with very little difficulty, and as soon as the worst portions had been surmounted the rope was rolled up, the capstan dismounted and a non-stop homeward run made under the critical gaze of Broadway's bicycle policemen and automobile experts at a speed of twelve miles an hour.

Arrangements for the demonstration were made by the Oldsmobile Company of New York, details being in the hands of George E. Crater, the holder of the American and English patents. It is announced that steps are to be taken to build the *canot-voiture* in America and to place it on sale here. The *Waterland* will form one of the attractions at the motor boat shows at New York, Boston and Chicago.

### PRESIDENT OPENS TENTH PARIS SHOW.

PARIS, Nov. 12.—President Fallieres formally opened the tenth annual automobile show in the Grand Palais and the huge temporary building on the Esplanade des Invalides this morning. Owing to it being the decennial exposition, the A. C. F. has decided on a more brilliant spectacular display than ever before, and will keep the exhibition open three weeks instead of two as formerly. Practically all the streets and squares within a three-quarter-mile radius have been included in a brilliant electric display, easily surpassing the outside illuminations of last year.

Within the main hall the electric decorations are of a particularly artistic and ingenious nature, the big glass dome being set with blue and gold lamps to give the effect of illuminated lace work. For the most part stands are those of last year with a few embellishments, illuminated wrought iron work predominating. De Dion is one of the few making an entire change with a Chinese pagoda in commemoration of the journey from Peking to Paris by one of their cars.

An attraction of the show is the "stand of honor" on which are displayed Nazzaro's Fiat, winner of the Grand Prix; the Peugeot which won the Coupe de la Presse, a Darracq racer, and a De Dion which traveled from Peking to Paris.

Prominent among the changes are shaft-driven cars for Dietrich and Panhard, high-tension magneto for Mercedes, a new gear box for the Renault, and several gasoline-electric town vehicles, one of the most important being a machine designed by Girardot, formerly of the C. G. V. firm.

Commercial vehicles of all kinds, motor boats, and machine tools and stationary plants in motion occupy a space on the Esplanade des Invalides equal to the entire Grand Palais. All the prominent American makers of machine tools show their products in motion. The commercial side of automobiling appears to have been enormously developed. Pleasure vehicles of moderate power are more to the fore than ever, while high-powered cars have in most cases undergone a slight reduction in price. For the first time cheap small-powered runabouts form a really interesting class from a business standpoint. During the show international conferences will be held on the use of alcohol, touring conditions, and motor boats. Arrangements have been made with all railroad companies for cheap transportation of those connected with the industry from the provinces to Paris.

### American Firms in the British Show.

LONDON, Nov. 11.—Without any very imposing ceremony, the sixth annual British motor exhibition, organized by the Royal Automobile Club and the Society of Motor Manufacturers and Traders, was thrown open to the public to-day and will continue until November 23. Although clashing with the Paris exhibition, there is no diminishing of interest in the British event, the big Olympia hall receiving a record attendance on the opening day. About six hundred pleasure vehicles are on show from every British firm and all the most important houses of France, Germany, Belgium and Italy. America is represented by Ford, Winston, White, Buick, and Reo.

## TINY RUNABOUTS SHOW RECORD SPEED

PARIS, Nov. 5.—Over forty miles an hour for a distance of nearly two hundred miles, by the aid of a tiny cylinder measuring 3.9 by 4.7 bore and stroke, is such a remarkable performance that it is not surprising our French friends find even their extensive stock of adjectives altogether too meager.

quately protect the course, \$2,800 having been spent by the organizers in obtaining the daily services of 800 troopers and a contingent of gendarmes and in barricading every part of the 21-mile course likely to be invaded by spectators.

Although the Sizaire & Naudin was an almost certain winner, interest in the race was keen throughout, the cars all being speedy and the men excellent drivers, most of them having earned a reputation on racing motorcycles. The dangerous would-be-racing element had been eliminated during the six preliminary days. Sizaire, on the little machine produced at his own factory, set a fast pace with an initial round at a speed of over forty miles an hour. Giupone, on a Lion-Peugeot, was only three minutes behind, with Rigal, on a two-cylinder Werner, Naudin on another Sizaire & Naudin, Cissac on an Alcyon, and half a dozen others finishing within five minutes of the leader.

Sizaire maintained his lead on the second round, with his partner, Naudin, five minutes behind him, and Peugeot, Werner and Alcyon all finished at intervals of a few seconds. When six of the nine rounds had been run off, Rigal and his Werner

got into first place, Sizaire, the favorite, being held up twenty minutes with a burst tire and a broken valve. Rigal, the ex-Darracq man, was not to remain at the head long, for Naudin captured the lead at the end of another round, and as soon as Sizaire had made his repairs he came to the attack with redoubled fury, doing the last three rounds at an average of forty-nine

NAUDIN, SON SIZAIRE & NAUDIN, WINNER OF VOITURETTE RACE.

The occasion was the final of the Coupe des Voiturettes, which started with 63 little runabouts on a 21-mile circuit near Rambouillet. After a six-day grind of 147 miles a day, at an average speed of not less than 18.6 miles an hour, 41 remained for the seventh day's speed test of 189 miles over the same circuit. The only result of the six days' preliminary running had been to eliminate a dozen machines which would have fallen out in half an hour of speed work, and to prove that any decently constructed machine, even if it has but one cylinder, can turn indefinitely at an average of eighteen miles an hour. True it had given the drivers an opportunity of studying every inch of the course, thus making possible a little faster speed than would have been attained otherwise; but its practical result was so slight that next year's "tour" will probably be a race only.

At intervals of thirty seconds the forty-one were sent away in the presence of not less than ten thousand spectators brought in from Paris by train or on the 783 automobiles which, according to the gendarme officer in charge, formed a line four kilometers in length. Money had not been spared to ade-

LION-PEUGEOT, FIRST FOR TEAM REGULARITY, THIRD FOR SPEED.

miles an hour, his driving calling forth unanimous praise.

There were some exciting scenes on the sharp turn known as the Fourche, for with forty-one machines on a twenty-one-mile course it was impossible for them to be far apart at any time. Two or three missed the turn and had to drop out of the day's race with either a broken wheel or a bent axle. Giuppone furnished a few seconds of intense excitement when his single-cylinder Lion-Peugeot swung completely round on the bend and entered into the fence. In a second the ex-motorcyclist had dropped in his reverse, swung round again and had avoided the end-on collision which seemed certain for a moment. Mechanical defects developed during the race were slight—three cases of defective ignition, two cars with broken valves, one with a broken gasoline tank, and one with a defective axle.

Sizaire finished first, but as he had been one of the earlier starters he had to drop behind his team-mate Naudin by a fraction over two minutes, the winner covering the nine rounds, or 189 miles, in 4:38:52, being an average of 40.6 miles an hour. Goux, on a single-cylinder Lion-Peugeot, finished third, one minute behind the second. Cissac, on an Alcyon, took fourth place, the Rigal, with one of the two-cylinder Werners, unfairly handicapped on weight, took fourth place. Although finishing first and second, Sizaire & Naudin did not win the regularity prize, the total time of their three cars being eleven minutes slower than the total elapsed time of the Lion-Peugeot team. So close was the competition, however, that had classification been arranged on the usual point basis Sizaire & Naudin, finishing 1, 2 and 13, would have got it with 16 points, compared with 18 for Lion-Peugeot, finishing third, sixth and ninth. No international race for big cars was ever so keenly contested as this speed test for machines which would have been considered toys two years ago. The first Lion-Peugeot had a regularity record equal to that of Nazzaro in the Grand Prix, the average difference between his rounds being less than a minute, and the difference between his initial round with a standing start and his fastest being four minutes. Of the 41 starters 32 finished the race, six firms having complete teams at the end of the seventh day.

So much surprise has been caused, even in technical circles, at the amount of power and speed obtainable from a diminutive cylinder that rumors of doping have gone abroad. The machines are certainly stock so far as their essential features are concerned, and there is no reason to believe that the gasoline received any additions. To put the matter completely at rest, however, the technical committee of the A. C. F. took a sample of the gasoline from the leading cars and after analysis will announce the result. Last year the maximum bore was limited to 4.7 inches; when the A. C. F. decided that a voiturette must not exceed 3.9 inches for a single cylinder, Sizaire & Naudin protested. They built a new car, and, although nearly an inch had been clipped off their bore, increased their average speed from 36 miles an hour to over 40.

A feature of the winning machines, all of which are selling from \$500 to \$800, is that over 90 per cent. of them were fitted with high-tension magneto. Simms-Bosch equipped the first six, other makes represented being Eiseman and Nilmelior. Coming just before the Paris salon, there is now an enormous boom in voiturettes, and under efficient management a record business should be created in popular runabouts.

## MONUMENT FOR WINNER OF FIRST AUTO RACE.

Twelve years after the Paris-Bordeaux and return race, and ten years after his death, Paris has decided to erect a monument to the memory of Emile Levassor, winner of the first automobile race the world ever saw. The site chosen is almost the exact spot on which Levassor stopped his car on the termination of the run from Bordeaux in the two-cylinder machine that asked for water every thirty miles, but which succeeded in proving to the world that there were some powers of movement in the automobile. Enthusiasts were few at that time, even Panhard, the partner of Levassor, having little faith in the new road vehicle they had produced.

Eight years ago an effort was made to erect a monument to the memory of Levassor, but the response was feeble; recently a renewed effort was made and subscriptions came in a flood,

MONUMENT TO LEVASSOR AT PORTE MAILLOT, PARIS.

notables in the automobile world and workers in the Panhard-Levassor factory contributing with eagerness. The monument, which will be inaugurated during the Salon, represents Levassor arriving at Paris at the end of the first automobile race, the winning car bearing No. 5 on its radiator.

## ENTRIES PLENTIFUL FOR 600-MILE RELIABILITY RUN

CHICAGO, Nov. 11.—Charles P. Root, chairman of the contest committee of the Chicago Motor Club, returned this morning from New York, bringing with him definite promises of at least eleven more entries for the 600-mile reliability run of the Motor Club the latter part of this month. With these eleven and the fourteen already in hand, the entry list, tentatively speaking, foots up to twenty-five cars, while there are assurances enough to make it seem more than probable that there will be

fifty in when the entries finally close on Thursday, November 21.

Those brought back by Chairman Root were from the Peerless, Autocar, White, Stevens-Duryea, Knox, Lozier and Locomobile. In some instances there are two and three cars promised, particularly in the case of the White Company, who are so intensely interested they are taking three cars. Two Locomobiles are on the fire and maybe two Stevens. The Knox talk two and the Lozier are debating the proposition.

## PHILADELPHIA SHOW SUCCESSFULLY IN PROGRESS

PHILADELPHIA, Nov. 12.—The seventh annual show of the Philadelphia Automobile Trades' Association, in the First Regiment Armory, was opened at 8 o'clock Saturday evening without any formal fuss and feathers. The attendance was a remarkably large one in view of the fact that Secretary Beck dealt out "paper" with a none too liberal hand. But the conditions are getting to be such that the practice of passing out "slows" to every Thomas, Richard, and Henry who may think he is entitled to them had to be cut out. People with real money in their hands nowadays clamor for a chance to purchase their way into the show, and with a building remarkable only for its utter inadequacy in size, it goes without saying that the show committee knew their business.

The advance in the show date from the snowball season to that of the harvest probably inspired the autumnal foliage idea in the decorative scheme, and that those in charge of that branch of the work made no mistake was evident from the exclamation of pleasure which accompanied the visitors' first view of the show from the entrance. To carry out the outdoor effect still further, all the booths are carpeted alike with grass-green burlap, while similar material of a gravel color represents the paths leading through the expanse of tree-dotted lawn. Overhead and around the side walls are draped thousands of yards of yellow and white bunting, and at night the usual lighting facilities of the armory are helped out by scores of universal lights ensconced in huge inverted flowers of a color to harmonize with the reds, yellows, and browns of the color scheme. There are no signs in evidence in the main hall, except the golden banners hanging from the roof or walls, and on which are the names of the cars in crimson lettering.

While Saturday night saw the exhibits still incomplete by reason of the fact that cars from the Garden show had not yet arrived, Monday midday saw all the exhibits in place.

Anyone who has ever endeavored to get a quart foot into a pint shoe will realize what the show committee was up against when it came to dividing up the space at its disposal among the exhibitors. This year the spaces were not assigned until all the applications had been filed, and none of the applicants was allowed more than two of the rather small spaces. True, the members of the association were given the preference when the locations were considered, but otherwise all hands were on an equal footing. And the fact that few complaints were heard is evidence that the committee has acted fairly with all. Some few of the accessories exhibitors claim to be unable to give an adequate display of their wares in the limited gallery spaces, and are holding individual shows at their respective salesrooms, all within a few minutes' walk of the armory. Other local dealers who delayed their applications until too late are doing likewise.

There are 58 exhibitors packed into the armory—32 showing 45 different makes of cars and 26 exhibiting accessories of various kinds, eleven of the latter being made up of tire displays. Two makes of motorcycles are exhibited. Of the 32 exhibits of complete cars and chassis in the drill hall, the majority are necessarily cramped owing to the desire of the exhibitors to show their respective lines as fully as possible. There are 110 complete cars and 22 chassis in the armory. Under the circumstances this is a most creditable showing.

To insure plenty of inspection room for those who contemplate buying, the committee has followed in the footsteps of the Garden show managers, announced Tuesday and Thursday as dollar admission days. The necessity for such an innovation was demonstrated at the last show, when the crowds were so thick as to seriously interfere with business.

To point out any exhibit as pre-eminent in a show where every effort is made to put all of them on an equal footing is, of course, impossible, but it is, nevertheless, a fact that the local crowds gather thickest where the "long, low, piratical craft" of

the roads are in evidence—those rakish runabouts and tourabouts which, while resembling racing cars in outward appearance, are equally as comfortable as the larger and more luxurious looking touring cars.

Among those concerns which either failed to apply for space in time or which preferred to run shows at their near-by salesrooms rather than attempt to do justice to their cars in cramped quarters are: A. G. Spalding & Bros., Stevens-Duryea, directly opposite the armory; Berl Segal, the newly-appointed Imperial agent, also opposite the armory; Panhard and Simplex, in the lobby of the Bellevue-Stratford Hotel; Studebaker, "on the street," having recently broken with their local agents; the Philadelphia Motor Car Company Frayer-Miller, at 236 North Broad street; Harry S. Houpt Company, 139 South Broad street; Dragon, 143 South Broad street. All of these concerns will make their salesrooms specially attractive to visitors during show week with music, flowers, and the "trimmin's."

This is the complete list of concerns exhibiting:

# REFINEMENTS OF THE AMERICAN AUTOMOBILE

By W. F. BRADLEY.

AS the mechanical features of the automobile attain higher and higher degrees of efficiency, more and more attention is being paid to refinements and finish. In the early days the automobilist asked for nothing more than a piece of machinery which would carry him over the roads at a faster rate than the

ELEGANCE AND PRACTICABILITY OF THE PIERCE LIMOUSINE.

horse; he willingly put up with obvious imperfections and was never exacting in the matter of body refinements.

To-day the automobilist must not only have a vehicle capable of carrying him from place to place without falter, but must be moved about with a host of refinements never dreamed of in connection with other modes of locomotion. An inspection of the models at the Madison Square show revealed the fact that not only is the public demand met, but manufacturers anticipate the desires of users, with improvements and refinements calculated to satisfy the most critical.

Instead of being satisfied with an open car all the year round, closed bodies are now deemed an absolute necessity by every user of an automobile with sufficient power to carry the extra weight. Limousine and landaulet bodies are more frequent than ever, some of the leading makers now producing as many closed as open bodies. Road conditions in this country are prejudicial to the extensive use of heavy closed bodies, with the result

OLD ENGLISH STAGE COACH ON APPERSON CHASSIS.

that the closed type is more or less of a city vehicle with few provisions for extensive touring.

An important exception is a closed touring car shown at the Pope-Toledo stand. It is a type of vehicle in frequent use over the better roads of Europe, but up to the present a complete stranger to America. The Pope-Toledo closed touring coach is a special limousine body mounted on the firm's standard four-cylinder 50-60-horsepower chassis. Ample protection is afforded the driver by a folding leather top and a swinging windshield with a leather apron attachment from its base to the top of the dashboard. Accommodation for luggage is provided by three special trunks on the top of the car, secured by straps to the metal gallery. On a rear platform two specially shaped trunks are carried; being inclosed in a black leather casing, they are completely protected from dust and rain and in no way mar the lines of the vehicle. It has not been forgotten that the exhaust from the engine can have a more evil effect on rear platform trunks than flying mud, for the fumes from the four cylinders of the Pope-Toledo are allowed to disperse nearly a couple of feet from the platform. Within the car two medium size dress suit cases can be carried under the front seats. They are prevented from shaking by being made to fit the space, are secured by a door, and the door hidden by the carriage trimmings, there being absolutely nothing to indicate their presence. With these seven trunks there is certainly ample luggage provision for an extensive tour by a full load of passengers.

The limousine is upholstered in gray broadcloth with whipcord trimmings, the upper portions of the walls and the ceiling being in polished white mahogany; the abolition of cloth is certainly an improvement, its presence not only harboring dust, but making an interior uncomfortably stuffy. The side windows let down, and the doors are fitted with wood screens provided with fine gauze panels to admit air. Among the refinements are electric lights, annunciator, and mirrors, which fold back against the wall, forming decorative panels when not in use. The external color scheme is pale yellow, black trimmings.

## Luxurious Refinement.

Kimball, of Chicago, has a very original body mounted on an Apperson chassis. Opinion is likely to be divided on the effectiveness of its

lines, but there will certainly be no two opinions regarding the excellent workmanship and careful finish of the old English stage coach. Side panels inclose the driver's seat, these panels being a continuance of the main body, with their base rounded off to harmonize with the rear of the body. Color scheme is black and red. At the rear of the body are a couple of lamps, showing a green and red light on the road and a white light inside. A projecting pocket between the two lamps is a reminiscence of more eventful days, when such a receptacle was needed to carry pistols and swords as a precaution against highway attacks. A tool box in the rear is of sufficiently ample dimensions to be useful, but not projecting more than four inches does not spoil the harmony of lines. Interior fittings are of the highest class, the refinements comprising speaking tube, electric lights, annunciator and convenient pockets.

As an example of luxuriousness and originality in internal fittings, the limousine on a 45-horsepower Pierce chassis stands

COIL UNDER DRIVER'S SEAT.

alone. In all structural features both chassis and body are of the standard type and are produced entirely at the Pierce factory. It is in the upholstery and fittings that special skill and labor have been exerted, H. M. Dawley, the Pierce Company's color designer, being specially responsible for the excellent result. All the upholstery below the line of the windows is carried out in a heavy buffalo hide ornamented by plain tooling. Above this line the trimming is hand-tooled Cordovan leather enriched with

dainty accents of colored lacquer and gold leaf. The same decorative scheme is worked out in the ceiling, also upholstered in leather, four lacquer and gold leaf bands radiating from a central electric dome. Harmonizing with the deep russet of the interior, all the interior metal is of an antique design and a sober gun-metal finish. Although an exceedingly dainty piece of work, the special Pierce limousine has the advantage of being thoroughly practical for constant use, leather being good wearing material and not a harbinger of dust. Judged from the standpoint of the user, the all-cloth style of upholstery is not the most satisfactory production.

Runabout bodies on powerful cars are to maintain their popularity, judging by the show exhibits. A general tendency is to

**TIRE IRON HINGED TO FOLD AGAINST BODY.**

put a double seat on the rear instead of the single rumble, this double seat being readily dismantlable, leaving a large platform for luggage. Developing this idea still further, the Stearns people have produced a five-passenger runabout, in which the seat to the left of the driver is placed several inches rearwards, and the two rear seats are a small detachable tonneau, entered from the right-hand side of the car only. Seating accommodation is provided for the chauffeur by means of a detachable seat hung over the running board by brackets to the side frame and strengthened by one leg. To make the position of the user more secure, a foot rest is fitted to the forward end of the running board. The entire seat can be removed by merely slackening a couple of bolts, and the rear seats can be taken off almost as readily, transforming the five-seater into a two-passenger runabout.

There are some original features in a demi-limousine made by Barr and fitted to a Matheson chassis. Bodywork is finished in a light natural wood, and the interior is upholstered in pigskin. The roof and upper portions of the interior are finished in plaited straw work, the general appearance of the car being one of delightful coolness for summer touring. The side windows let down into pockets and the glass screen between the rear compartment and the front seats can be raised or lowered at will. External finish is in harmony with the interior, the mud guards, for instance, being covered with the same material as the interior upholstery.

#### Minor Improvements Are Visible Everywhere.

Apart from the special bodies, some of which are certainly more attractive under the glitter of the limelight than they would be after a few weeks on the road, there is a wealth of improvements and refinements in bodies and fittings calculated to interest the genuine tourist. There is a strong tendency towards soberness in both color schemes and fittings; not only are gaudily painted touring bodies the exception, but there is a commendable tendency towards less glitter in the metal fittings of the car. This is clearly exemplified in a Studebaker and in a Thomas landaulet finished to special order with headlights, lamps, tank, steering column and all other external metal work in gun metal.

STRAW LINING, A FEATURE OF THE MATHESON.

Apart from the labor involved in keeping brasswork clean, its free use around the car has the effect of dazzling the driver to such an extent that some chauffeurs when driving in the face of the sun invariably smear dirt on their headlights. A large number of cars are shown with all metal work given a black finish, the result in nearly every case being pleasing. An excellent example is a Pope-Toledo touring car. On this machine, also, such metal work as door handles, robe rack, etc., has been covered with fine dark colored Morocco leather.

Provision has been made in a very large number of cases for more effectively keeping mud off the car, front mud guards being provided with a backing of either leather or metal, running to the side frame and completely protecting the bonnet. The use of a protector between running board and frame is a wise addition, for not only does it prevent mud being thrown upon the running board and the car, but it hides such unsightly organs as muffler, cables and transmission gear. On the better class closed vehicles, where its presence is almost a necessity, the guard is frequently in metal and not easily detachable. On touring cars leather fastened by means of buttons is the rule; on a certain proportion of the cars the attachment is made in such a rough and ready manner, and the brass buttons are so conspicuously brassy that cleanliness is only obtained at the expense of appearance. There are at least half a dozen cases, however, conspicuous among them being the Pope-Toledo, in which the leather apron is neatly cut and well fitted, the attachment being made by almost invisible buttons.

POPE-TOLEDO DESIGNED FOR COMFORTABLE TOURING.

DOUBLE LEATHER-FACED HINGED RUG RACK.

The trend towards simplicity and neatness is nowhere more pronounced than in the matter of dashboard arrangement. Fashion used to be to treat the driver to a display of automobile accessories. Studebaker, in one model, has gone to the other extreme, removing everything but a short circuit button, hardly visible a couple of feet away. Another model by the same firm has only a clock on the dashboard, surmounted by a small electric lamp reflecting onto the dial. Locomobile has a very neat dashboard arrangement, the only articles displayed being a small sight feed oiler, pump, and primer for carbureter—the whole group could be carried in the coat pocket. A similar clearing tendency is shown on the Lozier, the dashboard carrying the coil, a switch, and a small tubular oil indicator. Sunk

driver's seat. Oldsmobile also uses metal footboards covered with rubber except where the driver's feet rest.

**How Tools and Spares Are Accommodated.**

Provision for carrying tools and such supplies as the driver is likely to need is more generous than formerly. As an example, on the same Pope-Toledo model one running board carried a steel tool box with compartment for pump, tray with a complete set of tools displayed, each one having its own notch; on the opposite side is a smaller box, also of pressed steel, containing a storage battery, two oil cans, and one spare box. Oldsmobile also employs metal boxes. Studebaker has combined a tool box with the running board in such a way that it forms an easier step into the car and at the same time fills up the space between running board and frame. The usually empty space within a spare shoe is made to do service in the Pope-Toledo touring car, a leather case, the face of which is in three pieces fastened by a padlock, occupies this space, and forms a very convenient receptacle for inner tubes and other tire accessories. When not used for the purpose for which they were intended, tire irons are apt to be unnecessarily in the way. To avoid this on a Stearns touring car they are hinged at their extremity, allowing them to fold against the body when not required. One of the straps fits around a hook on the frame, keeping them securely held down. The Studebaker car was shown with the

Pope-Toledo.

Locomobile.

Lozier.

SIMPLIFICATION AND NEATNESS IN DASHBOARD ARRANGEMENT ON THREE LEADING CARS.

level with the sloping footboard is a pressure indicator. The pressure pump has been taken off the dashboard and placed in an equally accessible but less conspicuous position in the angle formed by the dash and the frame. A pleasing dash and footboard arrangement is that of the Pope-Toledo, where the footboards instead of being of wood covered with rubber, are two steel plates with an aluminum finish. The forward plate is considerably sloped, leaving a very short dash, in the center of which is an auxiliary gasoline tank with sight feed and handle for shutting off supply at its base. The only other article on the dash proper is a speed indicator, though in the sloping footboard there is a projecting level by which the flow of gasoline from the main tank is either shut off or opened. The coil is hung on the inside of one of the doors to the locker under the

inner arm of the iron loose on its sleeve, allowing it to be opened or closed to any desired width. A couple of broad brass bracelets fastened to the rear of a Lozier allowed for carrying a spare shoe there.

Small refinements for the comfort of travelers show more and more perfection. As an example of what is being done, the vertical knob by which the side doors of a touring car can be released generally necessitates a slit in the wood binder forming the top of the door. Rain enters and the spring mechanism becomes rusted. On two cars at least, a Studebaker and a Pope, this is avoided by a brass slide which automatically closes with the door, leaving no opening whatever. On the Stearns the two revolving armchairs are provided with a stop released by means of a convenient side lever. Instead of the cape top iron by the side of the forward seats being permanently fixed outboard, on the Lozier it is pivoted, folding inwards close to the upholstery; thus when not in use the iron is practically invisible. Another useful but minor improvement on the Lozier limousine is that the forward windows instead of letting down into pockets are made to slide one upon the other. A rack for rugs is a necessity in all touring cars, and forms a standard equipment. An improved design is attached to the Pope-Toledo car, consisting of two bars, both bound in leather, and made to hinge down when not in use.

Gasoline gauges on tanks are not very common as a standard equipment, only two cars in the show being fitted in this way. To protect against accidental puncturing of the rear gasoline tank, the Stearns runabout is equipped with a wood guard formed of laths laid on a metal frame and secured by a leather strap.

SLIDING COVER FOR LEVER OPERATING DOOR.

# SIMULTANEOUS BRAKING OF ALL FOUR WHEELS\*

By P. D'ESTIVAL.

FRONT-WHEEL braking has long been considered as offering a solution of the difficult problem of overcoming side-slip, particularly when the latter results from sudden stopping of the car as well as of better distributing tire wear. It is a subject of considerable general interest, that of retarding the car through brakes placed on the front wheels, as is evident from what has been aroused by the experiments of M. Arnoux. The center of gravity of a car always being located above the plane of its axles, its inertia combines with its weight, and both applied at the center of gravity, at the moment the brakes are applied there is a force set up, obliquely directed forward. It follows, as a consequence, that braking, whether effected at the front or rear wheels, always has the effect of overloading the front axle and relieving the rear axle of its load.

Hence, it seems logical, in order to obtain the best possible conditions of adherence, to retard the forward wheels, as they skid less than the rear wheels. However, there is considerable risk of blocking the front wheels and herein lies a serious danger, as in such a case they would no longer serve to direct the course of the car. Generally, the center of gravity is not sufficiently elevated to permit the overloading of the front axle, as a consequence of braking, to assume proportions greatly increasing the limit of adherence of the front wheels, which would be very dangerous, as the front wheels would then slide forward and the vehicle upset in attempting to turn about as a result.

It is evident from this brief exposition of the principles involved the sketch Fig. 2. A helical spring tends to maintain the brake substantially augmenting the negative acceleration, it may, on the other hand, be accompanied by dangerous consequences, particularly if the road surface be at all slippery, or if the car encounters an obstacle such as a (*dos d'âne*) "thank-you-ma'am." But the fact that the rear wheels carry the major part of the weight, something like 60 per cent. of the total, must be taken into consideration, and from this the conclusion is inevitable that the braking force on the front wheels must always be confined to a moderate value, not approaching a dangerous limit, and must also be applied at the same time as the rear brakes.

In the system devised by M. Hamon, he has allowed for imposing an amount of braking force to the wheels of each axle that shall be proportional to their static load. This is accomplished by means

of a central control, operated either by pedal or by a hand lever in connection with a system of flexible cables actuating the brakes themselves, with the intervention, in the case of the forward pair, of an apparatus for automatically applying the front wheel brakes should the steering gear accidentally give way. As shown by

FIG. 1.—Hamon front wheel brake.

FIGS. 3 and 4.—Equalizing apparatus and automatic stop.

the illustrations, Figs. 1 and 2, the front wheel brakes consist of a friction drum *B* attached to the spokes of the wheel. The constricting band *E* is provided with a series of wooden blocks lined with camel's hair felt *D*. The latter are articulated by a series of levers *G*, all of which are attached to a circular retainer, this being permitted to oscillate concentrically with the wheel itself within the limits allowed by the sector *H*. The controlling cable *J* is attached to the last lever of the series *G* after passing through a guide and the pulley on the end of the fixed piece *A*, which is solid with and practically a continuation of the steering spindle of the wheel, this being shown particularly by the sketch Fig 2. A helical spring tends to maintain the brake

FIG. 2.—Constructional details, front wheel.

FIG. 5.—Details of dashboard indicator of Hamon four-wheel brake.

off the drum constantly, the whole device being well protected by the sheet iron housing *F*.

Putting a tension on the cable causes the circle *G* to oscillate to the right, carrying with it the levers, and the band is applied, commencing at the left, the wooden segments coming into contact progressively. Figs. 3 and 4 illustrate the connecting device which is attached to the center of the front axle, and which serves in case of an accident to the steering gear to automatically apply the front wheel brakes and at the same time releases the control lever of the rear wheel brakes. It will also come into action in case the chauffeur loses his head in trying to avoid an obstacle and throws the wheel over too quickly, which might result in colliding with a second obstruction. The details of the apparatus are outlined in the sketches, Figs. 3 and 4. *A* is the housing attached to the front axle, while *B* is the sector and *C* the stop; *D* is the brake-controlling cable, and *E* is the drum on which the cable attached to the hand lever is wound, while *F*

\*Translation from *La Vie Automobile*, Paris, by Charles B. Hayward.

is the geared connection between the drum *E* and the sector *B*; *I* is the sheave over which the cable passes and *K* the shaft or axle of the drum *E*.

In order that the braking effort be not only efficient but entirely free from danger, it is necessary that the resistance created by each be identical in amount and simultaneously applied. In order to be able to know at any moment whether all the brakes of a car are in perfect working order, the inventor has evolved an additional device to be placed on the dash in plain sight of the driver, which permits the latter to tell at a glance the condition of the car's brakes. This device is very simple (see Fig. 5) and consists of two sets of opposing springs, *A* and *B*, attached by means of flexible cables directly to the springs, which serve to hold the front and rear brakes away from their respective drums. As soon as the brakes are properly regulated, the four pointers all assume a horizontal position, corresponding to zero. Regulation is accomplished very easily by means of turnbuckles, placed in the cables in an accessible position, any defect being considerably multiplied by the indicating hands. In order to avoid confusion as well as to protect the controlling cables, the latter are passed through flexible tubes fixed on with staples.

### A NEW LOW-TENSION MAGNETO.

It has long been considered somewhat strange that a concern having at its command such unequaled facilities for the production of such work as the General Electric Company, Schenectady, N. Y., should not have devoted its attention to the manufacture of ignition magnetos for automobile use. There has been a very marked increase in the adoption of this type of ignition during the past few years, so that the magneto is no longer considered merely as an adjunct to the highest-priced cars, but provision is made for it on the great majority of light cars, the selling price of which does not permit of its inclusion in their regular equipment. Reliability, ease of maintenance, simplicity, uniform sparking and freedom from trouble are qualities in which a well-built magneto has been found to excel. The machine is simple, self-contained, and eliminates much of the complicated wiring, besides being free to a very much greater extent from those petty annoyances that have long characterized the average ignition system, owing to the fact that its operation is purely mechanical and its speed does not exceed that of the motor.

The General Electric Company's experts have been making a study of the situation for some time past, and as the result of this, as well as the company's long experience in other lines of electrical work calling for the fulfillment of most exacting requirements, they have evolved a low tension magneto embodying all those desirable features of design and construction that experience has shown to be essential to the proper working of such a machine.

The general construction of the new magneto is of the most substantial nature and avoids all superfluous trimmings. Both the base and bearings are of bronze, finished with a sand blast, giving it an attractive appearance. A number of especially desirable features are noticeable in the construction of the armature. One end of the wire is brought out through the hollow shaft by means of steel conductor, the insulating bushing between the latter and the shaft being of bone and is, therefore, little affected by moisture or light. From this conductor it passes to a phosphor bronze helical spring and to the lower nut forming the outside terminal, thus avoiding any loose contacts. A hard

rubber cover with a knurled exterior is screwed to the bearing and houses the contact completely. The grounded side of the winding is firmly fastened to the core, and a carbon brush insures good contact between the winding and frame.

The magnets are compounded and are fastened by springing on to the frame and securing with a single screw on each side, thus minimizing the detrimental effects of drilling the members. In this most important part of the generator, the experience of its makers in producing millions of permanent magnets for meters and other apparatus over a period of many years, has proved invaluable, and it may be taken for granted that the magnets forming the field of the new machine are surpassed by none, whether of foreign or domestic origin. The demagnetizing of the field is prevented by making the armature core slightly overlap the pole gap when it is in the vertical position, thus avoiding a complete rupture of the permanent magnetic flux at any time. Both bearings are secured to the top and base of the frame rather than to the pole pieces.

Tests have shown that, on open circuit, the magneto's voltage is slightly in excess of 100 volts, this being easily obtained at a comparatively low speed, while a short-circuit current of approximately .4 ampere is available. In order to secure this high short-circuit current, the resistance of the armature winding has been made as low as possible, yet with a sufficient number of turns to give an adequate open-circuit voltage. It is the intention of the company to enter this branch of manufacturing on a large scale.

G. E. CO.'S NEW LOW-TENSION MAGNETO.

ESSENTIALS OF THE NEW MAGNETO.

### RUBBER IN ROAD DUST.

Everyone knows that in the dust of the London streets, among much more harmful constituents, there is much iron from the tires of wheels and the shoes of horses, says *The Autocar*. In fact, every road shows traces of iron from these sources. It struck us the other day when we were regarding somewhat sadly the flatness of a badly worn tire cover that there must be traces of rubber in the dust of an ordinary country road. Here was a tire which had once been circular in section which was now flat on the tread. The rubber had gone somewhere, and surely some of it must be found upon the roads which had taken their tribute.

Analyses of several samples of dust taken from different parts of the country show this conclusively. In the dust taken from the surface of a straight part of the road there was .042 per cent. of rubber, such as would come from a rubber tire. In the dust brushed from the road at a sharp corner there was .170 per cent. Careful examination of the sample reveals pieces both large and small of rubber tire, one piece being about 3-4 inch long and 1-2 inch wide. The result of this analysis is interesting in more ways than one. As we have said, it stands to sense that, as the tires wear, the rubber must go somewhere, and one would expect to find some of it on the road, though doubtless much of it is blown away in very finely divided particles. Another point shown by this investigation is that at a sharp corner the percentage of rubber in the road dust is more than four times as great as on a straight. It shows that not only are tires strained by corner work—a fact which everyone admits nowadays—but it also demonstrates that pieces are positively torn from them. When a cover has been in use for some time, and there are a number of surface cuts, any strain like sharply turning a corner puts so much work upon the parts of the cover that pieces are torn right out.

# A NEW GEARLESS CHANGE-SPEED MECHANISM

By ERNEST COLER.

A NEW type of gearless transmission, which is noteworthy in more than one respect, has been invented by Robert Miller, a mechanical engineer, of 26 Beech Terrace, New York City. Though originally designed for use in commercial vehicles the Miller transmission also is well adapted for use in pleasure vehicles. In the ordinary friction drive, in which two discs are placed at right angles, a great many speed ratios are theoretically possible, but the amount of slippage inseparable from this type of friction drive has prevented its general adoption.

In the Miller transmission all the thrusts are self-contained, involving no stresses upon the engine crankshaft, and a much heavier spring than is used in ordinary friction drives can be used for keeping the friction surfaces in contact. In the older friction drives, in which the discs are placed at right angles, there is mathematically only a single line of contact relied upon to produce the required amount of friction. The discs, moreover, must be made of soft material and are subject to wear.

FIG. 1.—Section and elevation of the Miller friction change-speed gear.

The appliance illustrated herewith depends upon the principle of the osculatory circle, which, according to the calculus, is a circle having three consecutive points in common. With a given curve, if these circles be made short cylinders, the points of contact become lines of contact and the area between these lines becomes a surface. This greater contact surface, of course, makes it possible to make the friction surface of more substantial material than that ordinarily used in friction drives. Aluminum, cast-iron, or steel, lined with leather or provided with cork inserts, can be utilized, giving an exceedingly efficient drive.

Another peculiarity of the right-angle disc drive is that the portion nearest the center of the horizontal surface moves with less velocity than the portion near the periphery, with the result that a certain amount of slipping or grinding cannot be avoided even in the best constructions of this kind. Since it is possible to enclose the Miller Gearless Change-Speed Mechanism entirely it is rendered immune to the effects of dust, mud, water, etc.

Another of its advantages is that it can be connected to a selective lever control; it may have a "clutch" pedal for disengaging the contact without changing the speed ratio, a feature that is valuable in rounding curves and in driving through congested traffic. The light weight of the contrivance, its extremely low cost of manufacture, its durability, and its ease of operation give the Miller device many advantages over other forms.

The mechanism is shown herewith as a three speeds forward and two speeds reverse combination, but reference to the cut shows that by providing additional "steps" more speeds are obtained.

The device is shown in detail in Figure 1, in which *a* is the end of the engine shaft, *b* a friction pulley mounted thereon; *c* is a step friction pulley (similar to the step-cone on a lathe). It is obvious that if the pulley *c* be mounted at *d* on the propeller shaft, with a universal joint and its slip joint, and clamped

FIG. 2.—Showing the relation of the parts on the third speed or direct drive.

against the pulley *b* the two will rotate together like an ordinary multiple-disc clutch. If now the pulley *c* be so placed that its surface *e* comes into contact with the surface *f* of pulley *b*, and sufficient pressure be applied to force them into contact, the pulley *c* will travel around the pulley *b* and the ratio of the speed will be the ratio between the diameters of the two pulleys. If, further, the pulley *c* be moved bodily backward, so that the surface *g* is above *f* and both come into contact, the pulley *c* will again revolve, but at a lower speed, because of the greater diameter of the pulley *g*.

FIG. 3.—Position of the members on the intermediate or second speed.

To obtain the reverse, the idler *h* is interposed between the pulleys *c* and *b*; forcing *c* against *h* forces *h* against *b*. The rotation of *b* being in the same direction, the direction of *c* will be reversed, and if the surface *g* of the pulley *c* be utilized, the low-speed reverse will be obtained. To lock the change-speed mechanism together for the high speed forward the surfaces *l* and *m* are brought into contact much in the manner in which a multiple-disc clutch is engaged.

The thrusts are self-contained, because if the pulley *c*, controlled by the link *o*, be forced into any of its notches against the link *p* (which contains the spring member) the pulling up on the spring is counter-balanced by the pushing down of the

FIG. 4.—Illustrating the positions of first or low speed, and the first reverse speed.

one pulley into the other. The clamping of the high-speed plates is similarly self-contained. With certain types of ball and roller bearings not only radial but also axial thrust can be taken, so that two bearings are sufficient for all purposes.

Figure 2 shows the outlines of a car with a wheelbase of about 90 inches, 30-inch wheels, equipped with an engine of about 16-horsepower located in front. Four views are shown, *A*, *B*, *C*, and *D*, and from the illustrations the relative positions of the change-speed mechanism giving three speeds forward and two speeds reverse can be observed. The propeller shaft is shown with a universal joint at each end, a slip joint being assumed.

# A LIGHT-WEIGHT "AIR BOTTLE" FROM FRANCE

TIRE pumps appear to be in danger of extinction. For a couple of years racing automobilists in both Europe and America have made use of compressed air tanks for inflation of tires, but the general public has remained true to the pump for want of a safe and practical appliance of the compressed air type.

The Michelin people have just brought out what they name their "air bottle," by means of which inflation, if not simplified, is certainly made less arduous than formerly. A compressed air tank weighing less than nine pounds, containing 450 liters of air compressed to 150 atmospheres, provides inflation for eight to ten large tires with no other labor than turning a tap. A couple of brackets hold the tank to the frame in the same manner as gas tanks so generally used in this country, or it may be kept in a box specially prepared for that purpose. The illustrations of the tank and its component parts are reproduced from the French review, *Omnia*.

FIG. 1.—Head of bottle, with rubber connection and pressure indicator. Manometer, for measuring quantity of air in tank.

Simple as the improvement may appear at first sight, its realization was not possible until enormous progress had been made in metallurgy. As every person is aware who has had occasion to handle them, the compressed air tanks used by tire firms at race meets and other occasions are so heavy as to make their use prohibitive on a car. Nine pounds for 450 liters, or nearly one hundred gallons of air at 150 atmospheres, is a triumph for the metal working industry.

A further difficulty in the use of a compressed air tank was the construction of an automatic outlet. If a pneumatic tire were linked up directly to a tank of air compressed to 150 atmospheres the intruding charge would inevitably cause a blowout, for the pneumatic tire is not made to withstand a pressure of much more than a dozen atmospheres. The outlet, or *détendeur*, as it has been named, needed to be simple in construction in order to be cheaply produced, for half the value of an appliance of this nature lies in its being procurable anywhere and an ubiquitous article must necessarily be sold at a moderate price.

FIG. 2.—Cross section of air outlet, showing safety valve.

The air contained in the tank A, Fig. 3, cannot escape through the outlet E and from there to the tire except when the plug D, mounted on the canal C, is unscrewed. Its passage then

is through the two small channels H, through C; and out by E. A very important rôle is played by the small disk P, a circular steel plate, slightly cone shaped. If the pressure in the tank is high, the steel disk is flattened against the head of the chamber in which it is lodged, allowing only a small amount of air to filter through. As the pressure in the tank diminishes, the steel disk assumes its normal shape by reason of its elasticity, thus allowing more air to pass through. This arrangement provides for a constant rate of outlet whatever the pressure of the air within the tank, the disk being calculated to allow of the filling of a tire in about three minutes. If the cock were opened suddenly the compressed air would momentarily flatten the disk, allowing only a slight outlet, the right proportion, however, being obtained automatically in a few seconds.

Although a pressure controller is fitted to the apparatus and overcharge could only be possible through carelessness, pro-

FIG. 3.—Cross of bottle head, showing details of pressure equaliser. Small drawing at right shows equaliser on enlarged scale.

vision has been made for automatically shutting off the flow of air when the pressure within the tire exceeds seventeen pounds. This is provided for by the paper washer O, Fig. 2, which will blow out at seventeen pounds pressure, allowing the air to escape through the opening F. A new washer can be inserted in a few moments. An independent indicator is provided, M, Fig. 1, to be screwed on at L, Fig. 1, in order to gauge the contents of the tank. A printed table pasted on the base of the tank indicates how many tires of a given size can be inflated with any given quantity of air.

## OBTAINING MAXIMUM MILEAGE FROM TIRES.

Many automobilists, especially those driving heavy cars, make it a rule never to repair an outer shoe, their contention being that the most economical method is to use a tire until it bursts and is incapable of further service. It is certain that many tires are thrown on one side while still capable of giving several hundred miles of service, users declaring that they prefer to lose a little of the life of a tire rather than run it to the last thread and sacrifice an air chamber also. There is no reason, however, why a tire should not be used until the fabric is worn through, for it is rare that it quits active service without giving signs of its approaching demise; and to avoid the loss of an air chamber also, the oldest one should be used in the old casings. As a precaution, any weak places on the interior should be patched, otherwise the tire may suddenly blow out, although no external signs of weakness of the fibers are present.

## LETTERS INTERESTING AND INSTRUCTIVE

## QUERIES CONCERNING HORSEPOWER, ETC.

Editor THE AUTOMOBILE:

[1959.]—Will you kindly give me some information in your "Letters Interesting and Instructive" column?

Horsepower, as I understand it, is a relative term. It may show itself either in speed or in ability to climb hills, depending to a certain extent on gear ratio. In what manner can the ordinary mortal who is not an expert mechanic ascertain whether a certain specified machine, rated at so many horsepower, will have the desired hill-climbing powers? In other words, if one is after a high-powered, low-speed machine, what formula can he follow to know what he is getting before he buys?

Is there any method to test a double Pittsfield coil, to ascertain the amperage that is being used in running the engine?

During a period of eight or ten months my coil was very economical in the use of dry batteries, consuming in that time only three sets, and giving the best of results and satisfaction. The platinum points were then slightly pitted and a friend (?) filed the points, but in so doing must have changed the adjustment or tension of the spring, as the coil has consumed more batteries in the last six weeks or two months than all the time before. Where shall I look for the adjustment, and how shall I make it? TREMBLER.

Walden, N. Y.

Formulae are of little or no value in such a case as this. Why not get into the machine and try it on some of the worst hills in the locality and note its performance? Agents are always willing to demonstrate their cars to the satisfaction of prospective purchasers, and "being shown" is worth more to the "ordinary mortal" than all the figuring he can possibly do. Take any high-powered modern car, and its hill-climbing capacity is almost entirely a matter of gear ratio. If its owner wishes to be able to climb unusually steep grades without dropping to a lower gear he must naturally sacrifice something of the car's speed on the level. But in choosing a car for hill climbing it is advisable not to gear it too low, as it then becomes necessary to race the engine in order to obtain anything more than a moderate speed on the level.

Take a coil-current tester, or low-reading ammeter, calibrated from 0 to 3 amperes by tenths and insert it in series in the primary of the coil to be tested—that is, connect one terminal of the instrument to the primary terminal of the coil and the other to the battery wire, so that all the current being used by the coil must pass through the ammeter. Start the engine and let it run, meanwhile adjusting the trembler of the coil until the instrument gives as low a reading as possible consistent with regular running of the engine. Do the same with the other coil. Probably the tremblers of your coils have been screwed down so that the current consumption is excessive, as any coil can be adjusted to take 3 to 5 amperes, though when working efficiently it should not require more than .3 to .8 ampere; some coils, however, will not work on less than one ampere or over. The ammeter mentioned can be procured from any supply dealer and is similar to the ordinary battery "tester."

## DATA ON FLYWHEELS FOR SIX-CYLINDER MOTOR.

Editor THE AUTOMOBILE:

[1960.]—Will you kindly inform me through the columns of "The Automobile" which is the best location for a flywheel on a six-cylinder engine, to give best results, and also about what weight should they be? W. S. REID.

Indianapolis, Ind.

Opinions differ as to what is exactly the best point to place the flywheel on a multi-cylindered engine, considered entirely from a theoretical point of view, but current practice favors the inboard end of the engine owing to the custom of combining the flywheel and clutch. Your second question is rather difficult to answer without other data than the fact that the engine has six cylinders. Its speed and size are somewhat important factors.

## EFFECT ON GEAR RATIO OF LARGER WHEELS.

Editor THE AUTOMOBILE:

[1961.]—I am an interested reader of "The Automobile," and have derived considerable benefit from the columns devoted to questions and answers, and should appreciate it if you will advise me in regard to the following in your next issue.

I have a 40 horsepower touring car, geared 3 to 1, with 34-inch wheels, and should like to know, in the event of putting on 36-inch wheels, how much higher it would gear the car, and how much speedier it would make it; also, if it would make any appreciable difference in the ability of the car to climb hills, as I do not want to make the change if it is likely to result in the car being weak on stiff grades, such as are encountered in general touring.

New York City.

SUBSCRIBER.

So far as the actual gear ratio of the car is concerned, putting larger wheels on cannot effect this. The road wheels will turn once for every three turns of the motor crankshaft regardless of the size of the driving wheels. To make an alteration in the gear ratio, it will be necessary to change the relative size of the bevel and driven pinions at the rear axle, or the chain sprockets, according to whether the car is double-chain or shaft-driven. Increasing the wheel size has the effect of increasing the gear ratio, of course, as owing to the greater size of the new wheels, the latter can make only .942 revolution in the same time that the 34-inch wheels would make a complete turn, this difference being accounted for by the greater speed attained. As the 34-inch wheel travels approximately 8.9 feet per revolution, at a motor speed of 1,000 r.p.m., it would cover about 2,970 feet per minute on the direct drive, or a little better than 33 miles per hour. The 36-inch wheel covers 9.4 feet per turn or 3,133 feet per minute, making the speed a little over 35 miles per hour at the same number of revolutions per minute. We should think the fitting of the larger wheels would make little appreciable difference in the car's ability to climb hills, particularly in view of the size of the motor, and in any event it cannot make the car *weak* whatever the grade may be. It may necessitate dropping to a lower gear on hills a little oftener than is now the case, but the increase in comfort as well as in the appearance of the car and the greater clearance should more than compensate for this.

## IS THE USE OF ACETYLENE GAS DANGEROUS?

Editor THE AUTOMOBILE:

[1962.]—Herbert G. Andrews, of the U. S. Title Guaranty & Indemnity Company of Brooklyn, advised us a few days ago at the show that, having read some letters in your paper of April 25 in regard to acetylene gas passing through copper tubes, he had decided not to use any more acetylene, as he was afraid of the danger of explosion. It seems that in a few of the other later papers there were some replies to this original letter, stating that acetylene gas passing through copper tubes was absolutely dangerous. We have never heard of this, and would be glad to have you take the matter up and enlighten your readers one way or the other.

AUTOLYTE MANUFACTURING COMPANY,

New York City.

A. H. Funke, Manager.

"When at the end of last season's use my car was put away, the lamps and generator were removed, leaving the rubber gas tubing which attached the copper tubing to the lamps and generator hanging loose with the ends open. A short time ago when overhauling the car, parts of the copper tubing were found bent in places, and upon taking the copper tubing in my hands to straighten these bends, was very much surprised to hear, as soon as the bending was started, a very considerable explosion and to see flames shoot out at the ends of these tubes. The explosion was nearly as large as a pistol discharge, and of sufficient force to tear loose the section of rubber dangling on the ends and throw it clear across the garage—a distance of 20 or 30 feet.

"There was no fire or open light to ignite any charge of gas that may have remained in the tube during its weeks of idleness, and as can well be imagined, the writer was considerably surprised. On bending the other copper tube leading to the other lamp, the explosion was repeated in exactly the same manner, and it seems quite improbable that the slight bending of the tube could

create sufficient frictional heat to ignite the gas that might have remained in these tubes."

This letter from B. A. Burtiss, Schenectady, N. Y., was published in the issue of THE AUTOMOBILE on March 14, 1907, and the letter of April 25, to which you refer, was but one of the many explanations offered by a number of correspondents. The first of these was from F. R. Covert, Hovington, Kan., and was published in the issue of April 11, 1907. It gives a layman's explanation of the phenomenon and is as follows:

"I have experimented to quite an extent with acetylene gas and generators, and find that acetylene gas leaves an explosive deposit on brass, copper and silver, which will explode under very slight friction. This deposit seems to be greatly increased if the generators are overworked, and the bot, freshly generated gas comes in contact with any of these metals. This certainly was the cause of the explosions Mr. Burtiss experienced while bending the copper tubes. The writer was quite badly burned at one time, five or six years ago, while removing a copper spray pipe from a large generator, the deposit igniting and causing the gas to explode, and has since often wondered why generator manufacturers use so much copper and brass under such circumstances."

The letter of April 25 referred to was from L. P. Lowe, San Francisco, Cal., and gave a somewhat fuller explanation of the matter, while a later correspondent, E. T. Senseny, M.D., St. Louis, Mo., gave the chemistry of the phenomenon. His letter follows:

"The accident was caused by the explosion of the cuprous salt of acetylene  $C_2H_2$ ,  $Cu_2O$ . It is a reddish-brown substance insoluble in water, but dissolves in hydrochloric acid, with the evolution of acetylene. When dry it loses the molecules of water and becomes carbide of copper,  $C_2Cu$ , and when dry it explodes violently at  $120^\circ F.$  or by friction. (See Keyser, Remsen, Newth on Acetylene and Its Compounds.) Dr. Keyser of Washington University is an authority on this subject."

A more detailed technical explanation of the chemistry of the matter was given by C. J. Frankforter, of Lincoln, Neb., in THE AUTOMOBILE of May 16, 1907.

#### A DISSERTATION ON THE SELDEN PATENT.

Editor THE AUTOMOBILE:

[1963.]—If the following contains sufficient of public interest, which I hope you will believe, you may publish it as a donation to public information, and as a tribute of one early inventor to another.

I am minded to take up the cudgels along with the writer in the October 10 issue, upon the Selden controversy. Knowing Selden as I did in 1880-85, at which time I, as well as he, had pursued every patent and important publication in the English language upon gas and steam engines, and road locomotion; I having practical and patent experience, and interested then, as now, both for and against sustaining patent claims.

Previous to this I had heard of a steam buggy at Albany fair about 1865. The first traction farm engine (in this country) was made by my townsmen about 1868, and I had helped to make the first steam wagon, which was used three years, carrying its load and another wagon anywhere.

That the automobile would have come without Selden, and the telephone without Graham Bell, I certainly believe, but that he labored toward its accomplishment with money, experiment and counsel I certainly know, and this was with discouragement and ridicule, as was the case with Edison, Bell (telephone), Goodyear, Howe and others.

Selden then had an engine of Lenoir principle; a two-cycle pump compression engine, and also multiple cylinder engines.

In 1882 I made an indicator, and took with his engine the first indicator diagrams (to the best of my knowledge) ever taken from a gas engine in this country; and these, reaching 225 pounds, were the first definite knowledge of the pressure or action of gas, except that an explosion was supposed to be "destructively and dangerously unmanageable." (Steam practice then was 60 pounds; now it is 100 to 250 pounds.)

This was previous to the blowing up of Rochester's streets by naphtha, and Selden's court testimony thereat, that naphtha would not explode; which evidence included the first public exposition of facts now well known, viz., that only critical mixtures of vapor with air are explosive. This occurred previous to the use of the first engine operated with liquid hydrocarbon; which he then predicted and was experimenting with, being, of course, ridiculed therefor.

One of my own inventions for the then future vehicle I was advised to patent, but believed that the term of my patent would

pass before such development would be realized, which was the case, but which feature was patented by a later inventor (my townsman), and now in general use upon the best cars, to his financial benefit.

The patent law reads that "an application for a patent is a legal reduction to practice," and, as an instance, Bell's crude patent is practically held to cover all transmission of speech by electricity; notwithstanding the fact that it was not operative until made so by others. Whereas Draughbach, who claimed to speak first, was decided against.

It should be remembered that where a patent is valid, that a monopoly to the extent of the patent exists as a matter of right; also that monopolies exercise both a beneficial and non-beneficial influence.

A peculiarity, in contrast to the defense: Mr. Selden does not talk much for publicity, but does his talking before the court; hence his legal success, as well as public obscurity. However interesting to the public, it is established that "pro-publicity loses the respect of the court," and prejudices it against that side of the case.

This, nor any amount of open controversy will not decide such a case, which, like that of Thaw, Haywood, and Bismarck's war problems, will not abide by public demonstrations, theorists, nor effusions of attorneys or elaborations of trials, but will turn upon features, like iron and blood, entirely different from which the valuable counsel laboriously promulgated.

The talk of the dear public, which is always right at first, and most of the way through, to find they were wrong at last, reminds me of Barnum's "The public want to be humbugged," and Prof. Sweet's "Things that are usually wrong" (in "The American Machinist"), and somebody else's adage, "the public knows it all beforehand, and finds it aint so behindhand," or "t'breashed out in public one way, and found legally to be another."

But it's lots of fun for the dear, fond public, so why stop them?  
Syracuse, N. Y. F. R. WILLIAMS.

#### MAKING BATTERIES IN THE FAR EAST.

Editor THE AUTOMOBILE:

[1964.]—It may be of interest to you to know this company has opened up a new industry in the Far East, for the manufacture of a first-class dry battery. The writer is an automobilist and constant reader of your paper, and after experiencing the troubles and tribulations of trying to operate machines in this country with batteries imported from the States, at least three months old to start with, decided him to put in an up-to-date factory and produce fresh dry cells.

The great trouble with the imported (American) cells is caused by sea voyage of 60 to 70 days, the internal consumption being increased by the great heat of the vessel's hold, and such cells seldom give over 15 amperes, and 10 to 12 are the average. We do not allow a cell to go on the market that does not show 25 amperes, and the average is above 27 amperes.

Automobiling is becoming more and more popular, and the demand for good dry cells is constantly increasing. We have a branch in Manila, and are just opening another in Sydney, New South Wales. We have in the city of Manila over 150 automobiles, which, I am sorry to say, are mostly of French manufacture.

ORIENTAL BATTERY COMPANY,

Hong Kong, China.

F. H. THOMPSON, General Manager.

#### EASE WITH WHICH MACHINES ARE STOLEN.

Editor THE AUTOMOBILE:

[1965.]—It might be of some news interest and also put others on the alert to know of my misfortune and afterward good fortune.

On the night of September 25 a thief broke into the garage at this place and took my auto, a Model F Buick. Every effort was exerted to get the machine back, with the result that it was recovered on October 4. It shows how easily a machine can be taken and gotten away without the thief being caught at the time. The machine was taken just twenty-eight miles, left in the timber, and even the farmer on whose place the machine was left knew nothing about it. I have the Buick agency at this place.

Iola, Kan.

P. S. MITCHELL, M.D.

#### FOR FLORIDIAN WHO WANTS A WIDE GAUGE.

Editor THE AUTOMOBILE:

[1966.]—In your issue of October 10 a letter appears, signed T. A. Ansley, inquiring for a runabout built for Florida roads. The Cadillac Company manufactures a runabout with the standard Southern gauge. If he will address the Cook Auto Co., Orlando, Fla., he will be able to obtain all the information he desires on the subject.

R. J. THOMPSON.

Cleveland, O.

## CONSTRUCTIONAL DETAILS OF THE ELLSWORTH

IN the course of several years' experience, every autoist, particularly if he be technically skilled, evolves in his own mind the design of a car embodying his own ideas of construction, but it is not given to many to be able to see such an ideal materialized. However, this has been the case with John M.

Ellsworth, and on that account the new Ellsworth car is unique. Commercialism has been relegated to the background entirely in its design and construction, the prime object of its builder being to see those features that have appealed to him as superior to existing forms perpetuated on a car of his own design. To do this Mr. Ellsworth has established his own shop, employing a large force of skilled workmen, and collaborating with Thomas J. Fay,

CYLINDER CASTING AND VALVE ASSEMBLY.

has turned out a car which is of far more than passing interest, owing to the many novel features of design and construction that it involves. The materials employed are chrome steel, chrome nickel steel and chrome vanadium steel wherever alloy steels could be utilized, all such parts being in the shape of die forgings.

The motor is of the four-cylinder type, mounted forward and attached directly to the side members of the main frame, no sub-frame being employed. It is placed slightly to the rear of the forward axle, so that the face of the radiator about comes flush with the latter. This not only greatly enhances the appearance of the car as a whole, but places the entire weight between the two axles, in addition to facilitating the steering. That the motor is of the four-cylinder vertical, water-cooled type is the only conventional thing about it, as in practically every other respect it differs considerably from standard practice as represented by current types and involves numerous features of merit which have been very cleverly worked out. For instance, as will be apparent from the accompanying photographs, the cylinders are separately cast with open water-jackets, subsequently closed with light steel plates at either side and screwed on. The valves are oppositely disposed, being located in outboard chambers of the Mercedes type, and are mechanically operated from above by a novel superimposed form of camshaft, completely encased in an aluminum housing, the details of this part of the engine also being well illustrated by the photographs. The rocker

arms are of special design, are made of bronze and work on Hess-Bright ball bearings, which also characterize the majority of the other moving parts of the motor. This is true of the crankshaft, which is of the built-up type, supported on very liberal sized bearings inclosed in special bronze retainers, which house them completely. The camshaft is driven from the crankshaft through a vertical shaft and bevel gearing, placed forward. Such accessories as the oil and water pumps are driven from separate shafts, the latter being located to the right and the former below the vertical shaft mentioned, as will be plain in

BUILT-UP CRANKSHAFT SHOWING LIBERAL SIZE OF BALL-BEARINGS.

the forward view of the motor shown at the bottom of this page. An extension of the camshaft, which is carried through the dash at the rear, is utilized for driving the magneto, which, together with the carbureter, is located in the specially recessed dashboard in a very accessible position. The crankcase is of a special aluminum alloy, which is also true of the remaining housings about the motor, the dash and the gear-case. In fact, throughout every part of the car it has been the aim of the designers' and builders to use only the very finest materials obtainable,

the alloy steels having to pass a flat bending test under a powerful steam hammer without showing the slightest signs of rupture at the 180 degree bend. With the same purpose in view, every bearing on the car, with the single exception of the wrist-pins and big ends of the connecting rods, is of the Hess-Bright annular ball type. All these bearings are housed and separately lubricated, and in every instance sizes considerably in excess of the maker's ratings have been employed. In the case of the camshaft the ball bearings are submerged in oil, and in every instance great pains have been taken to mount these bearings in a manner that marks a considerable advance. On the chrome-nickel steel crankshaft, the design of which is patented by Mr. Ellsworth, the ball bearings are fit-

SHOWING FORWARD SUSPENSION

AND DETAILS OF OILING SYSTEM.

ted directly to the crank members without the intervention of any packing member and are inclosed in special bronze housings.

Though the placing of the motor accessories such as the carbureter and magneto will seem strange at first, it is doubtless the experience of every autoist that protection against the elements

CHANGE-SPEED GEAR AND DIFFERENTIAL.

is an essential thing in their case, and the dashboard location combines this with accessibility.

The low-tension timer for the battery side of the ignition system is also located in the same place, and it will be noted that the duplicate spark plugs are set in the under side of the inlet valve. The design of the inlet manifold is particularly noteworthy as representing such a departure from current practice.

But the features of interest of the new Ellsworth are not confined to the motor by any means. The clutch is of a special type evolved by Messrs. Ellsworth and Fay and on which they have taken out patents. It consists of a hardened drum attached to the driven shaft and a spiral band made fast to the driving member, so arranged as to be constricted at will. This drum is tapered, as is also true of the spiral band, the whip end of the latter being pinched between the drum and the housing. The result is that the band constricts automatically when its other end is held as the motor tends to wind it up on the drum. Chrome nickel steel is used throughout in its construction, and the clutch as a whole runs in oil, so that it can be made to slip at will, or hold as tightly as if the shaft were a single piece of metal.

The change-speed gear is of the sliding type, giving four speeds forward and reverse by the usual method of selective operation, and, as in the motor, special pains have been taken with the mounting of the bearings, which are all of the annular ball type, while the shafts and pinions are of the finest alloy steel. The gear-set and differential are inclosed in the same aluminum

housing, final drive being by means of side chains, though it is the intention of the builders to construct a shaft-driven type of car for those who prefer it. The braking system is of especial interest, as in addition to the regular differential and emergency brakes the car is equipped with an auxiliary differential brake. All the brake drums are of special steel and are of unusually liberal proportions. The surfaces are heat treated to make them more durable, while the bands are of special steel lined with pure annealed copper, ingenious and simple means for making adjustments being provided and also for equalizing, which is effected

BALL-BEARING BRONZE ROCKER ARMS WHICH ACTUATE THE VALVES.

without the introduction of an inertia component, such as a heavy cross bar or similar means.

The chassis suspension consists of full elliptic springs in the rear, with three-quarter elliptics in front, but the latter are of unusual design in that their ends are riveted directly to the ends of the frame without the use of dumb irons or shackles. They

ALUMINUM HOUSING FOR CAMSHAFT AND ROCKER-ARMS.

arc of Krupp alloy steel and are made without any joints. The steering gear has been constructed throughout of similar material, and great pains have been taken to make it absolutely proof against breakdown. Considerable ingenuity is revealed in the design of the control, which consists of four small bronze levers

with finger ends. These levers pass through racks in a housing located directly beneath the mahogany trimmed steering wheel, and do not rotate with it. They may be operated by either hand at will and are so located with regard to the wheel rim that they can be used without removing the hand from its accustomed position. Speaking of the steering gear, every part of this, such as the lever arms, connecting rods and the like, are all of chrome nickel steel, the cross rod being made of a solid bar of this material accurately drilled out. It is absolutely free from uncertain joints or fastenings, but, despite its alloy-steel, jointless construction, safety devices are provided in addition, and the makers feel quite certain that nothing has been left undone to evolve a steering gear that shall be as safe and reliable under all conditions as it is possible to build. The result of using alloy steels is manifest in the low weight of 1,900 pounds.

NOVEL INTAKE MANIFOLD, SIDE VIEW OF CAMSHAFT DRIVE AND WATER CONNECTION.

## AMONG THE BUSY CLUBS OF AUTODOM

### ST. PAUL'S CLUB IS GROWING AND PROSPEROUS.

ST. PAUL, MINN., Nov. 11.—Perhaps the most enthusiastic meeting in the history of the St. Paul Automobile Club was the annual meeting held on Monday of last week at the rooms of the Commercial Club, when officers were elected for the ensuing year, and plans for the future of the organization, especially those pertaining to the new clubhouse, were discussed. The building committee reported that the clubrooms are about ready and will be turned over to the club next week. The rooms will not be ready for occupancy for some little time yet, as the decorating has not yet been done, nor is the furniture ready. The furniture has been contracted for, however, and so has the heating. The lighting contract has not yet been awarded. The furniture will be mostly of the mission style. The club is planning to hold a formal house-warming towards the latter part of December, or as soon as the clubrooms have been entirely decorated and furnished. In March the State Association will hold its annual meeting in the St. Paul clubrooms, and it is planned to make this a notable function.

H. S. Johnson, the secretary, who has been one of the most persistent workers in behalf of the club, will probably have a paid assistant to help him with his work and take charge of the building as soon as the club moves to its new quarters. The treasurer reported that there is about \$2,000 in the treasury, \$1,000 having been made on the race meet held last summer. The secretary reported that there are now 140 members in the club, against eleven at this time last year.

The following officers were elected: President, Reuben Warner; vice-president, R. M. Neely; secretary, H. S. Johnson; treasurer, W. O. Washburn; board of directors, Oscar L. Taylor, F. B. Lynch, T. W. Ingersoll, and W. R. Edwards.

Plans are being formulated for an automobile day during the convention of the Mystic Shriners in St. Paul next July, and for a race meet at the State fair grounds.

### HARRISBURG PLANNING 1908 ENDURANCE RUN.

HARRISBURG, PA., Nov. 11.—Plans for the annual endurance run of the Motor Club of Harrisburg, which will be held early next May, are now being made by the contest committee. Three routes have been mentioned, but the one leading to Baltimore via Hagerstown, with the return via York and Lancaster, seems to be the favorite. The second route mentioned is to Philadelphia via Allentown, while the third leads through the coal regions with the night stop at Wilkes-Barre. Many cars are expected to be entered in the contest, which will be made much stricter than last year in order to prevent any abundance of perfect scores. The four cars tied for the touring car trophy last year will enter the next contest as competitors for both the 1907 and 1908 trophies. R. H. Johnston, of New York, will likely act as referee for the run.

Active steps taken by the Motor Club of Harrisburg for the betterment of roads in the vicinity of the Capital City of Pennsylvania has led to operations on three country roads and plans for the building of a five-mile boulevard along the Susquehanna river, just north of the city.

The Motor Club has appropriated a sum of money to pay off part of the debt on the Fort Hunter turnpike with a view of converting the road into a sixty-foot wide boulevard.

### WILKINSBURG CLUB HOLDS ANNUAL ELECTION.

WILKINSBURG, PA., Nov. 11.—The annual election of the Wilkinsburg Automobile Club resulted in choosing the following board of officers for the ensuing year: President, Dr. W. R. Stephens; vice-president, S. L. Smith; secretary and treasurer, Dr. W. C. Cook.

### SUCCESS ASSURED FOR THE NEW JERSEY RUN.

NEWARK, N. J., Nov. 11.—Conducted on lines entirely different from those that have been customary in previous events of a like nature, the 24-hour endurance run of the New Jersey Automobile and Motor Club, which will be held on Friday and Saturday of the present week, November 15-16, promises to be a great success. Over twenty entries have been received to date and more are promised. The contest will be a road test, the contestants being required to traverse a circuit five times, going through Newark, Bloomfield, Glen Ridge, Montclair, Verona, Caldwell, Pine Brook, Parsippany, Rockaway, Dover, Kenil, Morristown, Bernardsville, Far Hills, Bedminster, Somerville, Bound Brook, Dunellen, Plainfield, Scotch Plains, Springfield and Irvington. The single circuit is about ninety miles in length.

The competing cars will start from the clubhouse, 1034 Broad street, Newark, between 2 and 3 o'clock Friday afternoon. Contestants are limited to members of the club, and a silver cup will be awarded to each competitor finishing with a perfect score. Each car will carry an official observer and its full complement of passengers. Traffic regulations must be strictly observed. A system of penalizations has been provided for, including a loss of two points for arriving at a control either three minutes before or after the scheduled time, and a loss of four points for stopping the motor to make repairs. There will be no class division, all cars, irrespective of horsepower or selling price, being eligible. The race committee in charge of the event consists of W. C. Shanley, N. B. Niblette, J. H. Wood, Paul E. Heller, L. T. Wiss, F. A. Croselmir and H. A. Bunnell.

The first issue of the *Motor Record*, the official organ of the New Jersey Automobile and Motor Club, has made its appearance. William S. Thomas, a well-known Newark newspaper man, is responsible for the appearance of the *Record*, which is well printed and newsy, and will go to every member of the club, which now has some 800 members.

### VISITING AUTOISTS HAVE 48 HOURS IN PHILA.

PHILADELPHIA, Nov. 11.—The Automobile Club of Philadelphia is notifying its members of the recent announcement of the Director of Public Safety that he intends to enforce the State ordinance requiring drivers of automobiles in Philadelphia to obtain a license from his department. This license is obtained at the Bureau of Boiler Inspection at a cost of \$2 for the first year and \$1 for renewals for each succeeding year. Visiting autoists from other cities are given forty-eight hours grace while in Philadelphia. There has been much opposition expressed by Quaker City autoists to the special tax imposed by the city, and its enforcement will undoubtedly prove a very unpopular measure. Far seeing automobilists hope its enforcement will result in its

The club committee on routes and sign posts has arranged for the erection of numerous signs at different points and also have signs bearing the words "Blow Your Horn" for cross roads which the local authorities deem dangerous. The State law provides that a gong or other alarm shall be sounded when approaching any street or road crossing.

### NEW CLUB IS ORGANIZED AT JOHNSTOWN, PA.

JOHNSTOWN, PA., Nov. 11.—This city now has a full-fledged auto organization, known as the Johnstown Automobile Club. The movement for the club's organization was started some time ago, and culminated in meeting for organization, at which the following board of officers were elected: President, Charles S. Price; vice-president, W. F. Murdock; secretary, Walter Dowling; treasurer, John L. Stibich; board of trustees, J. Leon Replogle, Dr. Francis Schill, Jr., and F. B. Cook. The members of the new organization are very enthusiastic over the pros-

pects and will at once establish a permanent headquarters. The club will undoubtedly become a member of the Pennsylvania Motor Federation in the near future.

#### CINCINNATI'S CLUB HAS AN ORGAN.

CINCINNATI, Nov. 11.—The first number of the Automobile Club of Cincinnati *Bulletin* has made its appearance, and contains some interesting statistics which show that a very large proportion of the autoists of this city belong to the organization. There have been issued since the first of the year 750 license tags to automobile users in Cincinnati, and as the club has a membership of 230 it will be seen that almost one-third of the automobile owners in the city are club members. The report of the sign-board committee of the club shows that during the past season 148 signs have been erected on the roads in the vicinity.

#### ANNUAL CLIMB OF RHODE ISLAND A. C., NOV. 16.

PROVIDENCE, R. I., Nov. 11.—The annual hill climb of the Rhode Island Automobile Club for the Prescott Knight trophy will take place Saturday next on the hill leading to the residence of the donor at Riverpoint. The Knight cup has been won twice by L. F. N. Baldwin, and should he be successful again on Saturday, the trophy will become his permanent property. Eugene M. Swain is chairman of the committee having the event in charge.

#### AURORA AUTOISTS WANT CLUBHOUSE.

AURORA, ILL., Nov. 11.—There is well authenticated talk among the members of the Aurora Automobile Club in favor of a clubhouse, and as soon as a suitable location can be secured a house will be leased and furnished. The Aurora club is growing fast and the necessity for new quarters is becoming more than ever apparent.

#### ROAD WEARING OBSERVATIONS OF AN AUTOIST.

Angus Sinclair, president of the New Jersey Automobile and Motor Club, tells, in the club's official organ, *The Motor Record*, of his experiments in the matter of alleged damage to roads by automobiles:

When a fast-running automobile is seen rushing along in a cloud of dust, the beholder naturally receives the impression that the car is carrying with it a considerable portion of the roadway material, and that a succession of cars would quickly sweep bare the surface of the highway. This is the superficial impression, and it has given rise to persistent lamentations concerning the destructive action of automobiles in disturbing the materials which bind the surface of macadam roads together. Things are not always what they seem, as every engineer and investigator finds out many times, so moved by knowledge of mistakes being made through superficial impressions, I determined to make some tests to ascertain with some exactness how much the surface of the roadway is moved by passing vehicles.

Some portions of the main road leading from Springfield towards Scotch Plains have the surface badly attenuated by the action of horses' feet, and the individual stones stand out like blunt spurs or short harrow teeth. Last September during a dry time I collected about one hundred pounds of road dust and spread it over part of one of these bare spots and watched results. I examined the place every third or fourth day, and at the end of eleven days could distinguish no particular difference. On the twelfth day after the experiment began there was a heavy shower of rain. Having been caught in the shower near the scene of my experiment, I proceeded to the spot to examine the effects of the rain, and found that numerous miniature river beds had been cut through the dust covering. When the surface dried the covering scattered flat again, but it had become decidedly thinner. About a week later there was a severe rain storm, and when I ventured the trip to examine my road covering, all traces of my labor had been obliterated.

From constant observations of the Munn avenue, East Orange, road surface, which was covered with a dust-preventative material some months ago, I am persuaded that the real need for the preservation of our roads is a surface covering that will prevent the rain from washing away the binding material.

## THE AUTOMOBILE CALENDAR. AMERICAN.

### Shows and Meetings.

- Nov. 16-23.....—Baltimore, Third Annual Automobile Exhibition, Automobile Dealers' Association. B. R. Johnson, manager, Piper Building.
- Nov. 30-Dec. 7.—Chicago, Coliseum and First Regt. Armory, Eighth Annual National Automobile Show, and First Annual Commercial Vehicle Show, National Association of Automobile Manufacturers.
- Dec. 9-14.....—Detroit, Riverview Park Auditorium, Detroit Automobile Dealers' Association. LeRoy Pelletier, manager.
- Dec. 9-14.....—San Francisco, Coliseum, First Annual Automobile Show, Automobile Dealers of California. N. R. Cooper, manager.
- Dec. 14-21.....—St. Louis, Mo., Jai Alai Building, Second Annual Auto Show, St. Louis Automobile Manufacturers' and Dealers' Association. D. M. Strauss, manager.
- Dec. 28-Jan. 4.—New York City, Madison Square Garden, Importers' Salon. C. R. Mabley, manager.
- Feb. 10-15.....—Detroit, Light Guard Armory, Tri-State Automobile and Sporting Goods Association, Seventh Annual Show.
- Mar. 7-14.....—Boston, Mechanics' Building and Horticultural Hall, Boston Automobile Dealers' Association. Chester I. Campbell, manager, 5 Park Square.
- Mar. 9-14.....—Buffalo, Convention Hall, Sixth Annual Automobile Show, Automobile Club of Buffalo. Dai H. Lewie, manager.
- Mar. 21-23.....—Toronto, Canada, St. Lawrence Arena, Automobile Show. R. M. Jaffray, manager.
- Apr. 5-12.....—Montreal, Canada, Arena, Third Annual Automobile and Sportsman's Show. R. M. Jaffray, Mgr.

### Motor Boat Shows.

- Dec. 7-14.....—New York City, Grand Central Palace, National Association of Engine and Boat Manufacturers. Chester I. Campbell, manager, 5 Park Square, Boston.
- Jan. 1-8.....—Chicago, Coliseum, National Association of Engine and Boat Manufacturers. Chester I. Campbell, manager, 5 Park Square, Boston.
- Jan. 25-Feb. 1.—Boston, Mechanics' Building, National Association of Engine and Boat Manufacturers. Chester I. Campbell, manager, 5 Park Square, Boston.
- Feb. 3-8.....—Buffalo, Convention Hall, First Annual Power Boat and Sportsman's Show, auspices of Buffalo Launch Club. Dai H. Lewis, manager.
- Feb. 20-Mar. 7.—New York City, Madison Square Garden, Fourteenth Annual Motor Boat and Sportsman's Show.

### Races, Hill-Climbs, Etc.

- Nov. 15-16.....—Newark, N. J., 24-hour Endurance Run, Automobile Club of New Jersey.
- Nov. 16.....—Providence, Annual Hill Climb, Rhode Island Automobile Club.
- Nov. 26-28.....—Chicago, Three-day 600-mile Reliability Race, Chicago Motor Club.

## FOREIGN.

### Shows.

- Nov. 12-Dec. 1.—Paris, Exposition Decennale de l'Automobile, Grand Palais, Esplanade des Invalides, Automobile Club of France.
- Nov. 22-30.....—London, Agricultural Hall, Stanley Show.
- Dec. 5-22.....—Berlin, Germany, Automobile Show.
- Dec. 21-Jan. 2.—Brussels, Show, Palace of the Cinquantenaire.
- Jan. 18-Feb. 2, '08—Turin, Italy, Fifth International Automobile Exhibition, Palace of Fine Arts, Valentino Park, Automobile Club of Turin.
- Mar. 21-23.....—London, Agricultural Hall, Cordingley's Show.

### Races, Hill-Climbs, Etc.

- Dec. 8.....—Paris, Straightaway Aeroplane Speed Test, auspices of "L'Auto."
- Dec. 13.....—Paris, Competition for Agricultural Automobiles, auspices of "L'Auto."
- May 12, 1908....—Sicily, Targa Florio, Automobile Club of Italy.
- June 20-July 5.—Grand Prix, Dieppe Circuit, Automobile Club of France. (Exact date to be announced.)
- August, 1908....—France, Coupe de la Presse, Automobile Club of France. (Exact date to be announced.)

# Autoing in Northern Africa:

PART III

TUNIS, CARTHAGE and  
EASTERN TUNISIA  
By C. H. Jones

IN ONE OF THE PRINCIPAL STREETS OF TUNIS.

THE city of Tunis is less attractively located than Algiers. Low-lying on a deep inlet of the sea known as the Lake of Tunis, even its "casbah" or citadel, which stands on the highest land within its limits, is hardly distinguishable from the hovering mass of buildings when the city is viewed from a distance. Yet for the visitor from America or Europe it possesses more of interest. In the first place, it is less Franch and more Oriental. The Arab city within the old walls has wisely been left almost intact, while the foreign quarter has been built outside the walls, mostly on the made land redeemed from the swamp that formerly extended from the city walls to the water's edge of the "lake." In the second place, the native life and customs have been less interfered with. Equally effective in essentials, the French domination is less obvious and pervasive here than in Algiers. As soon as he steps from the hotel into the street, the visitor can feel no doubt that he is in the real East. In the passing throng, giving it its distinctive character, are Arabs and Barbères, Bedouins from the desert, negroes black as ebony and clothed in gorgeous colors, women swathed in white but with faces veiled in black (these are the Arab women), others in white silk and unveiled (these are Jewesses). If he enters the old Arab city he finds bazars (called "souks"), smaller but nearly as interesting as those of Constantinople or Cairo—the perfumers, the jewelers, the tailors, the carpet merchants, the shoemakers, the sellers of dry-goods, the silk-weavers, the blacksmiths, the brassware merchants, each trade in its own "souk," yet all grouped together in a wonderful tangle of intersecting alleys or arcades; the shops, about as large as a hall bedroom at home, but crowded with workers

and tradesmen. If he walks the narrow thoroughfares leading from the gates in the old city wall, he is jostled by a motley crowd that will remind him of the changes in a kaleidoscope.

In its history Tunis reaches back into the twilight of antiquity, and, unlike its more famous neighbor, Carthage, it has been continuously a more or less prosperous city ever since it was settled by the Phœnicians, about 860 B. C.

There are four garages, of which one is spacious and well equipped, and a still more spacious one is nearly completed. Tires and other usual auto supplies may be obtained at these garages at slightly enhanced prices, and by telegraphing almost anything may be had from Paris in four or five days. The usual price of gasoline is 60 centimes per liter, but it may be bought at 50 centimes, the same as in Algiers. In all respects Tunis is most attractive for a stay and as a center for automobile excursions, the first of which will pretty certainly be to Carthage.

### Fêtes at Carthage, "the City That Is No More."

With all who are even superficially acquainted with history there is no name save Rome that wakes such an echo in the imagination as that of Carthage. And the fate that anciently befell the two rivals still persists. Rome remains, and promises to remain, the "Eternal City." "Carthage is no more." Every visitor to Tunis who learns that he is so near the site of Carthage is eager to go there. But disappointment awaits him. To the casual observation the only conspicuous object that now marks the site is the painfully new and modern-looking Cathedral of St. Louis, which surmounts the summit of the Byrsa, where stood the citadel of both Punic and Roman Carthage. Of the ancient mistress of the Mediterranean there are fewer and less striking remains than of many a fifth-rate city whose ruins still serve to remind us of the Roman dominion in Africa.

The site of Carthage—there is not even a village there now—is 16 kilometers from Tunis by an excellent macadamized road. From Tunis itself and all along the road the white mass of the Cathedral of St. Louis catches the eye, and on arriving the first impulse is to climb the hill on which it stands.

The best preserved of its ruins is the ancient Roman Theater, and here "a fête antique" took place on April 3 at which our party was fortunate enough to be present.

### Some Seaside Resorts "Around the Lake."

As already explained, the city of Tunis is not situated on the sea, or even on the Gulf of Tunis, but on the inner curve of a nearly land-locked bay, known locally as El Bahira, or the Lake of Tunis. It is a very shallow body of water, through which the Canal of Tunis has been constructed to the entrance of the Gulf at La Goulette, thus making a seaport of Tunis. A pleasant morning or afternoon excursion may be made by circling the lake and visiting interesting places near its shores.

One afternoon about 2 o'clock we left Tunis by the Avenue de Paris and turning to the right just before reaching the Belvedere, the pretty park of Tunis skirted the northern shore of the lake to La Marsa (20 kilometers). La Marsa stands on the site of ancient Megara, which was part of Punic and Roman Carthage, but it is now simply a pretty seaside resort, with many villas set in gardens and the favorite residence of the present Bey of Tunis. About two miles beyond is Sidi-bou-Said, the summit of Cape Carthage and extending down the steep slope to the sea. Its houses are all whitewashed, and from sea or land it is perhaps the most conspicuous landmark near Tunis. The lighthouse here, built on a Roman foundation, towers 440 feet above the sea, and the tomb of the saint for whom the town is named is so venerated that it is an object of Mussulman pilgrimage from all parts of North Africa.

Returning to La Marsa from Sidi-bou-Said, we turned eastward and by a road passing the foot of the hill of Carthage soon reached and traversed the frequented seaside resorts of Khéreddine and La Kram, containing a spacious casino and numerous detached villas that are occupied in summer by wealthy Tunisians. Next comes La Goulette, formerly the port of Tunis, but

deprived of its commercial importance by the construction of the ship canal and harbor of Tunis. Nearly every building in it was constructed with stones taken from the ruins of Carthage. Here we crossed the canal on a primitive looking ferryboat and proceeded over a sort of dyke or causeway 10 kilometers to Radès, situated between the Lake of Tunis and the sea and a favorite summer resort of the French residents of Tunis.

Some ten kilometers east of Radès by a rather rough road, situated directly on the shore of the Gulf of Tunis, is Hammam Lif, the most frequented bathing resort in Algeria or Tunisia. The sea bathing on a very fine sandy beach attracts summer visitors in large numbers, and the hot springs draw winter visitors. From Hammam Lif an excellent road, diverging to the left just where the road from Radès enters the town, leads in 16 kilometers direct to Tunis, which we reached about 6 P. M. The total distance was about 65 kilometers (40 1-2 miles).

#### A Peep at Bizerte, the Rival of Gib.

A whole day should be given to the excursion to Bizerte, and if the weather is favorable, and if the fields are carpeted as when we made it with the marvelous variety of spring wild flowers that abound in North Africa, the day will prove an enjoyable one.

There are two routes to Bizerte. For the direct and better one we left Tunis by the gate Bab Bou Saadoun, followed the tramway to the Bardo (3 kilometers), and there, at the fork of the road, took the one to the right. From the Bardo to the hamlet of La Sebalah (15 kilometers from Tunis) the road passes through olive plantations and then through a well cultivated but very sparsely populated region almost due northeast. At 30 kilometers the road climbs and then descends a long, low hill, notable as the site of ancient Utica, which was a flourishing Phœnician colony before Tunis and Carthage were founded, but of which the only vestiges that now remain are scarcely traceable ruins of the theater, amphitheater, and a Carthaginian palace. A large modern farm and a small Arab village occupy part of the site. Just beyond kilometer post 25, at the hamlet of Protville, the river Medjerda, the largest in Tunisia, is crossed on a stone bridge, the roadway of which is in very bad condition, threatening to tires.

As far as kilometer post 29 the road between Tunis and Bizerte is uneven—good in spots and bad for equal distances. Then it improves and is very good for the rest of the way to Bizerte. Eight kilometers beyond Utica, at kilometer post 38, the road forks. The straight road leads to Porto Farina, once the chief naval port of Tunis, now noted only for its extensive fisheries. A road thence leads up the coast to Bizerte. The left fork is the direct road to Bizerte, which by this route is 63 kilometers from Tunis.

Bizerte is, next to Toulon, the most important naval station of France in the Mediterranean. It was planned with a view to neutralizing the importance of Gibraltar, and has done so.

We were surprised to find at Bizerte a large and good hotel (the Grand), connected with which is a garage where gasoline may be had for 60 centimes per liter (48 cents a gallon). The new town, or foreign quarter, is well built in the modern French style, but the old Arab village is more interesting to the visitor. We passed through its narrow streets on our way to the Corniche Road, as the drive of 20 kilometers around Cape Bizerte is called. The drive borders the sea for most of the distance, and after it turns inland affords interesting rear and interior views of some of the powerful sea batteries.

The return journey to Tunis may be made via Mateur and Tebourka, but it is much longer (116 kilometers) and we could not learn that it offers anything of interest en route. We preferred to leave the Mateur route by a road that turns off to the left just beyond kilometer post number 8. This took us through Ferryville and almost completely encircled the Lake of Bizerte, enabling us to see what a spacious harbor it affords. We rejoined the direct route near kilometer post 41, and turning to the right, reached Tunis at sunset.

Bizerte is almost due north of Tunis. Zaghouan lies due south, at a distance of 52 kilometers by the most direct route via La Mohammédia. The road was in very bad condition when we made the excursion on April 20, and there is little of interest en route. La Mohammédia (14 kilometers), now a vast ruin or collection of ruins, was a country residence built by Ahmed Bey, containing accommodations for his entire court, with quarters for 15,000 soldiers, and surrounded by a fortified wall. On his death it was abandoned by his successor and the natives plundered and partly demolished it. Just beyond kilometer post 17 the road runs close beside the impressive ruins of the ancient Roman aqueduct that conveyed water from the mountains near Zaghouan to Carthage and Tunis, and crosses a stream on a stone bridge whose piers were those of the aqueduct.

#### Southward to Carthage's Water Source 1,900 Years Ago.

Zaghouan itself, standing on the site of a Roman town whose name is unknown and of which only a triumphal arch remains, is a dirty village of about 2,000 inhabitants, mostly Arabs, but surrounded by gardens of flowers and fruit trees. What makes it worth a visit is the great spring which gushes forth at the

MAP OF TUNIS SHOWING ROUTE TO THE GREAT DESERT.

foot of the Djebel (Mount) Zaghouan, about a mile and a half from the village. This spring supplied Carthage with water 1,900 years ago, as it now supplies modern Tunis and the towns near the site of Carthage.

The return journey to Tunis may be made via Sainte Marie-du-Zit and Cretéville, the route being somewhat longer (73 kilometers), but more picturesque, with steep ascents and descents through the mountains near Sainte Marie-du-Zit and a winding road along the valley of Mornag.

We made the excursion across Cape Bon to Nabeul one afternoon, starting about 2:30 P. M., but if we had had any correct idea of the distance we should assuredly have allowed ourselves more time. The misinformation on the strength of which we started affords a good illustration of the difficulties automobilists encounter here in the effort to obtain exact facts even about comparatively nearby places. Nothing helpful regarding distances could be found in the books, and when we asked at the hotel we were told that Nabeul was "about twice as far as Hammam Lif," through which we pass in going there. This would have made the distance to Nabeul 32 kilometers, and the total distance there and back 64 kilometers. We learned by experience that the distance to Nabeul is 79 kilometers and the round trip there and back 158 kilometers, a difference which might have cost us dear, for we started with insufficient gasoline for such a trip. Fortunately we found that the hotel at Nabeul

keeps a supply, which was not only salvation for us, but shows how great a change has recently occurred in this respect. Three years ago gasoline could be obtained in Tunisia and Algeria only in the half-dozen larger cities. Now it is found for sale even in a small town like Nabeul remote from any highway of travel, and at a price slightly less than that charged in Tunis.

The road to Nabeul is good all the way except a few kilometers where the roadmenders were getting ready for repairs. From Hammam Lif it runs directly across the base of Cape Bon, passing a few meager villages, of which Grombalia (37 kilometers from Tunis) is the most important. Just beyond kilometer post 60, after climbing a low hill, we came in sight of the sea—the Eastern Mediterranean that stretches away to the shores of Asia Minor. To the left, in the distance, nestling on the shore and gleaming white in strong sunlight, lay Hammamet, a pretty summer resort that is becoming popular with Tunisians. Turning sharply to the left at kilometer post 61, we skirted Hammamet without entering the town, and after a swift run of 11 kilometers reached Nabeul, the ancient Neapolis. Nabeul is noted for the native pottery made there and for the perfumes which are distilled from the roses, geraniums, jessamine and orange flowers that grow in the gardens by which the town is surrounded. The climate is exceptionally mild, and Nabeul is becoming known as a health resort for both summer and winter visitors.

Beyond Nabeul the road continues north and is good as far as Kourba, the ancient Colony Tulio. Farther north still are Menzel and Kelibia (ancient Clypea), and then comes Cape Bon, the northern tip of Africa. In Roman times this whole peninsula of Cape Bon was densely populated, and ruins abound everywhere. Some of these would no doubt reward excavation. Our excursion ended at Nabeul, and in spite of swift running darkness overtook us before we reached Tunis.

#### Remote Tunisian Roads Shame Those of America.

The excursion to Sousse, Sfax and Gabès is by far the most important and most interesting that can be made from Tunis. To do it justice requires from five to seven days, and the longer time may be spent profitably. Our party gave eight days to it in all, and made two separate attempts. The first time we went to Sousse and Kairouan and were driven back by a spell of bad weather that lasted two weeks. When the weather settled we went all the way to Gabès and back, making the trip in five days.

The road is the best leading out of Tunis; with the exception of about 15 kilometers, throughout the entire distance to Gabès (405 kilometers, 253 miles), it is excellent. In fact, one of the marvels of the trip is to find here in remote Africa, in a country for the most part sparsely populated, 250 miles of road far better than any similar length of road in the entire United States—a road upon which work is constantly going on and which is kept in better condition than the drives of Central Park.

As far as kilometer post 61, where the turn-off is made to Hammamet and Nabeul, the route is the same as the preceding. For 25 kilometers beyond the fork, and in fact nearly all the way to Sousse, the road runs close along the margin of the sea, through a country perfectly level and mostly devoted to farming. Eufidaville (96 miles from Tunis) is a flourishing European colony, interesting because it is the center of a property of 300,000 acres, a quarrel concerning which between a French company and the natives led to the French occupation of Tunisia.

Sousse (140 kilometers) is a very attractive little city, with several hotels in the European quarter, one of which (the Grand) is quite good, and a garage and repair shop where gasoline can be had at 60 centimes per liter.

#### Kairouan, the Sacred City on the Plain.

At the Arab village of M'Saken, 15 kilometers beyond Sousse, a road diverges to the right from the main highway and leads in 46 kilometers to Kairouan. The road is good for most of the distance, but in places extremely bad; and when we made the journey on April 13 it was at its worst, because of repairs in progress and because of a tropical storm which burst upon us

AVENUE JULES FERRY—ONE OF TUNIS' BEST STREETS.

on our way back to Sousse, converting a portion of the road into a soft, spongy swamp, well nigh impassable, and making of every depression in the roadbed a pool of muddy water.

Kairouan is one of the sacred cities of the Mohammedan world, and like Mecca is an object of pilgrimage to the faithful. As we approached it across the level plain it lifted in the air like a mirage, with minarets and domes defined against a murky sky-line, and its walls and buildings looking white and phantom-like under the cloudy heavens. It was founded in 670 by the conqueror and saint, Sidi Okba, whose tomb we had visited near Biskra, and the site selected is said to have been a dense forest infested with serpents and wild beasts, which were driven out by a miracle. It has remained until now almost exclusively a native city, with scarcely 200 foreign residents, and because of this it is peculiarly interesting. Another source of interest is that it has the finest mosques in Tunisia or Algeria, and these are the only mosques in Tunisia that can be visited by Christians or Jews.

The "souks" or native shops offer little of interest after those of Tunis, but are wholly native. The Hotel Splendide, outside the walls, has a garage at which gasoline is sold at 70 centimes per liter (about 56 cents a gallon).

#### More First Century Ruins in Trip to Sfax and Gabès.

The road from Sousse to Sfax (130 kilometers) is excellent for automobiling and leads through one of the richest farming regions of Tunisia, where vast quantities of wheat are grown with the scant yield of about 8 bushels to the acre, and where extensive olive plantations are seen at frequent intervals. The only object of special interest en route is the Coliseum of El Djem (64 kilometers from Sousse), and that is of very great interest, for it is one of the finest Roman ruins in existence. El Djem is a squalid Arab village standing on the site of the

PERFORMANCE IN THE ANCIENT CARTHAGINIAN THEATER.

ANCIENT CISTERN AND MODERN CHURCH AT CARTHAGE.

ancient Roman city of Thysdrus, of which not a visible vestige remains save this wonderful amphitheater towering massive and solitary above the plain. The Coliseum dates from the time of the Emperor Gordian the Elder, whose reign began in 236 A. D. Its greater axis is 489 feet and its smaller 407 feet. Its circumference exceeds 1,200 feet, and it could seat 60,000 spectators. Its state of preservation is about the same as that of Rome's Coliseum, although it was used by the Arabs for centuries as a fortress and in later times as a quarry from which columns and blocks of stone were carried off for the building of bridges and houses. When the time comes for excavating the site of ancient Thysdrus it is probable that other interesting ruins will be found, but none to compare in majesty with this gigantic monument of a city that must have been both rich and populous to support such a place of amusement. Our Metropolitan Opera House could be set down inside its arena.

Sfax is another of the Phœnician cities that were established along this part of the Mediterranean coast in the eighth and ninth centuries B.C. By the Romans it was called Taparura, and this was its name until the Arab conquest in the eighth century A. D. Its modern name is said to be derived from the Arab word *fakons* (cucumber). Since the French occupation in 1881 it has grown rapidly and is now the second city of Tunisia in population and commercial importance. The old city, within the crenellated and bastioned walls, is still wholly Arab and on that account interesting. The French and European quarter has grown up outside the walls, around the new port. There are two fairly good hotels and a garage where gasoline is sold for 55 centimes per liter.

Here we were told that gasoline could not be obtained at Gabès, so we carried with us in the tonneau enough to make the round trip. We found, however, that the Grand Hotel de Gabès has it for sale at 80 centimes per liter (about 64 cents a gallon). It was explained to us that the high price is due to the fact that it must be brought by camel most of the distance from Sfax. There is no railroad between Sousse and Sfax. A ramshackle automobile omnibus makes the trip daily (fare 20 francs). From Sfax a narrow-gauge railroad has been constructed which runs alongside the Gabès road for 35 kilometers to Mahares, and then runs southwest to Gafsa. The nearest point to Gabès on this railroad is Graïba, 80 kilometers distant, and between this point and Gabès an automobile of similar type of those of the Sfax-Gabès line makes the round trip twice a week (fare each way 15 francs).

The road from Sfax to Gabès (135 kilometers) is excellent and runs most of the way close to the sea. There is nothing of interest en route, and the country traversed is singularly featureless and desolate. For about half the distance when we traveled it on April 28 there were vast fields of stunted grain; then a grazing country thinly sprinkled with innutritious-looking grass, and the last 50 kilometers were in the Desert of Sahara, which here has none of the interesting features of the portion of it traversed in going to Biskra.

If one has been to Biskra or intends going there, this trip from Sfax to Gabès and return is not worth the trouble. But if Biskra is not on the program, then this journey is worth making simply to have the experience of traversing a wide expanse of desert and emerging from it into the delicious cool green of an oasis. And the oasis of Gabès is, on the whole, the most beautiful we had seen.

#### The Novelty of Reposing in a Desert Oasis.

The weather had changed before we left Tunis, and the seasonable warmth which there had succeeded the persistent cold and rain became intolerable heat in the desert. The journey to Gabès one afternoon and the return next day to Sfax was made in a temperature that, in the arid, treeless, and shadeless desert, must have exceeded 120 degrees, and this was aggravated by a sirocco or hot wind from the south. The oppressive heat deterred us from going to Madenine, 80 kilometers beyond Gabès, to which point the national route extends. In ordinary weather that extension of the trip is well worth while, for the opportunity it affords of seeing the curious habitations of the Troglodytes or cave dwellers. Their caves are dug out of the sides of a cliff, and comprise as many as five different floors or stories. In some cases there is an outside staircase, but these are usually absent, and the occupants of the upper floors climb up to them by the aid of projecting stones.

As we were prevented by the heat from going to Madenine. Gabès was the southernmost point of our tour in Algeria and Tunisia. It is about 150 kilometers farther south than Biskra and nearly as far south as Tougourt. Four days after our return to Tunis, namely, on May 3, our automobile was hoisted to the deck of the Compagnie Transatlantique steamer *Ville de Naples*, and on the morning of May 5 we landed again in Marseilles. We found it more expensive to get out of Africa than to get in. The cost of transporting the automobile from Tunis to Marseilles, including embarkation and landing fees, was 264 francs (\$52.80). From the time of our landing in Algiers to our embarkation at Tunis we had motored 3,242 kilometers or 2,027 miles, of which 1,280 kilometers were in Algeria and 1,962 in Tunisia.

In fairness to those who may be induced by what has been written in these articles to undertake a similar trip a word should be said regarding the steamer service between North Africa and European ports. It is very bad. Not only are the steamers small and nearly all of them old, but a worse drawback is found in the methods of management. The rule which is practically universal on other sea routes, that if you buy two first-class tickets you are entitled to a cabin or stateroom, is not recognized on these lines. Nor is anything gained by registering in advance. For the steamer by which we came from Tunis to Marseilles we were registered three weeks before the date of sailing, and our names were first on the list, yet the ladies of our party were jammed into staterooms each with two other women occupants, and the men were treated in like fashion. Even so small attention as would be required to assign the first applicants to lower berths was not given to the matter. The whole efforts of the company's agents appeared to be concentrated upon the program of filling each separate berth in the steamer with a paying passenger, and provided that was accomplished nothing else mattered. The question of the passengers' comfort and convenience appeared to receive absolutely no consideration. There is less excuse for this because the rates of passage are high; much higher relatively than on the palatial steamers of the Havre-New York line. However attractive motoring in North Africa might be found to be, either as read of in a descriptive account or as a personal experience, it can never become really popular with automobilists until the steamer service to and fro is greatly improved.

#### A Summing Up of Advantages and Drawbacks.

What the writer experienced in the important matter of weather has already been set forth in these articles. Making all due allowance for an exceptional season (and we were as-

sured by everybody that it was exceptional), it is nevertheless unquestionably true that North Africa should be shunned in winter by the automobilist for the same reason that New England is shunned—because it will subject him to great discomfort and will offer few compensations. The American enthusiast for whom the usual motoring season does not suffice would better seek his winter recreation in France. He will find the roads there in pretty much the same condition as in Algeria and the hotels far more comfortable. Outside of Algiers and Tunis no hotels in North Africa possess any facilities for warming their interiors, and even in spring the rooms—including the sitting and dining rooms—are penetratingly cold. The only time to motor for pleasure in Algeria and Tunis is in March and April (from the 15th of March to the end of April), or in October and November. If spring is chosen the entry should be made at Tunis and the Tunisian excursions made before proceeding to Algeria; the tour which the writer has described should be taken in reverse. The reason for this is that the climate of level Tunisia is milder than that of mountainous Algeria. If the fall

#### Algeria and Tunis Safer than East-side New York.

When the writer mentioned in New York his intention of venturing upon a motor trip in Algeria, solicitous friends, with visions of Raisuli in their mind's eye, urged that the men of our party provide themselves with serviceable revolvers. We did so, and as a matter of fact we had about as much use for them as we would have in a drive down Fifth avenue. The natives were everywhere peaceable, orderly, and even friendly; actuated by a mild curiosity concerning ourselves and the car; watchful of all we did because of its strangeness to them; obliging with information when they could be made to understand what we wanted to know; and always ready to lend a helping hand when assistance was needed. A kindlier people than the Arabs it would be difficult to find anywhere, and even in the country of the historically fierce Kabyles we did not on a single occasion experience a discourtesy. The writer would rather motor with a party of ladies over any portion of the route he had described than down one of the East Side avenues in New York City on a Sunday afternoon. In this connection

[ARAB WOMAN OF BETTER CLASS.

BEDOUIN FAMILY OF FOUR.

RICH JEWISH WOMAN OF TUNIS.

is chosen, then the tour as the writer has outlined it could hardly be improved upon from the climatic point of view.

The roads have also been described with the minuteness that automobilists are apt to desire. In summary it may be said of them that, as a whole, they are surprisingly and remarkably good—far better than could reasonably be expected in a portion of the world so remote from countries that are supposed to have a monopoly of civilization. In all accessible portions of Algeria and Tunisia the writer traveled more than 2,000 miles. In the entire United States there are not half as many miles of macadamized road that would bear comparison with these in point of engineering and up-keep. The only important section of road traversed that could fairly be described as bad was that across the Desert of Sahara, between El Kantara and Biskra, and in another two years one of the best roads in Africa will link those two places.

At present there are only four cities in Algeria and Tunisia where tires and other automobile requisites can be found. These are Algiers, Constantine, Bone, and Tunis. As recently as three years ago there were few places outside of these four cities where gasoline was kept for sale. Now it can be found in almost all towns of any size along the usual routes of travel. It is expensive, its price ranging from 50 centimes per liter in Algiers and Tunis (about 40 cents a gallon) to a franc per liter at Biskra (about 80 cents a gallon). In the interior the price will no doubt gradually fall as the demand increases, but on account of taxes it is not likely to fall below 50 or 60 centimes per liter anywhere.

one point should be emphasized. It is indispensable that on such a trip at least one member of the party shall be able to speak French fluently. A surprisingly large number of the natives, even in the remote interior, understand French, but in no other language save Arabic or Berber is it possible to communicate with them. Of English or any other European language they know not a word.

Is it worth while? is a question which has already been put to the writer many times and which it is difficult to answer categorically. For any motorist with whom comfort is a primary consideration, it is not worth while. Until one has motored over most of England, Scotland, substantially all of France, a large part of Germany, the Austrian Tyrol, Holland, Northern Italy, and such portions of Switzerland as can be visited, it would be wiser to postpone the tour of North Africa. On the other hand, if one has the sporting instinct, or the craving for alien scenes and strange peoples, then it is worth while. As the writer recalls the cost, the trouble of getting there and of getting away, the perplexities and anxieties of the trip, and the deep disappointment with the climate, he is inclined to say "no." But when in the reminiscence he recalls the strange land and scenes, the undying fascination of Oriental people, the wonder and the mystery of the desert, the gorgeous colors of the fervid East, the sense of remoteness from all the habitudes of ordinary life, he is inclined to content himself with saying that those who like what he has described will find an automobile trip through the classical and picturesque countries of Algeria and Tunisia exactly what they like and a great deal of it.

**What Scientific Investigation Has Accomplished.** Few automobilists realize the extreme crudity of the electrical apparatus which the automobile designer found was the only thing to be had but a comparatively few years ago. True, electrical ignition was far from being new, and its component essentials, such as the spark plug, the make-and-break ignitor, the timer, and the induction coil, had all been used to a greater or less extent in stationary and marine practice, but that they were about as far from being up to the requirements of automobile service as they possibly could be, and still work, will be the recollection of every autoist whose experience extends back that far. The induction coils of those days could not be adjusted to take less than two or three amperes, timers were both mechanically and electrically defective, and the same thing applied to the plugs, so that in combination they rapidly wasted two-thirds of the output of the battery, and, generally, the sins of the entire ignition system were laid at the door of the latter.

The story of the development that has taken place in the interim is a long one, and each one of the advances, simple as it may now seem in retrospect, not only required considerable study to bring about, but also much painstaking investigation to fathom, for the manner in which improvement was to be made was frequently a sealed book. There were so many unsuspected causes of failure that nothing short of the constant application and study that has been given the subject during the past few years could ever have sufficed to bring about the tremendous advance

that has been made, and for the accomplishment of which the manufacturers of ignition accessories have been almost altogether responsible. The hit-and-miss methods that had characterized the early investigations of pioneer automobile builders were given up in favor of the more exacting and resultful study of the laboratory and the outcome is a matter of common knowledge.

**Is Toll-paying a Solution of the Road Problem?**

Judging from the frequency with which special automobile toll-road projects spring up in various parts of the country and the tenacity with which the idea that such roads would prove a profitable investment is entertained, it would seem as if there were more in the subject than appears at first sight. On principle, the average autoist strenuously objects to being taxed for the use of the road to a greater extent than others who enjoy the same privilege, and with reason, but whether he would so object to paying a nominal sum to make use of a highway constructed and maintained especially for his benefit is another matter. Doubtless he would be only too glad to be able to take advantage of such an opportunity, and be quite willing to contribute toward the support of such a road in sufficient numbers to make it economically possible. The Long Island Motor Parkway is an illustration in point, and it will doubtless form a model for a great many others of similar nature when completed.

This brings to light the question as to whether the automobile toll-road may not eventually prove to be the stepping stone to that vastly improved state of affairs that is universally hoped for—a time when not alone all roads will be considerably more deserving of the name, but when there shall no longer be any prejudice on the part of one class of road users against another, particularly when that other is representative of progress. It goes without saying that ultimately nine-tenths of all road traffic will consist of automobiles, and tolls would then be abolished as a natural sequence. The plan of making those responsible for the improvement pay for it is somewhat anomalous, but unfortunately that is frequently the only manner in which such improvements can be brought about expeditiously.

**Use of Objectionable Signaling Devices.**

Rising above the multitudinous and indescribable noises of city traffic, which the urban dweller has come to endure as a matter of course, his ears are now assailed by weird groans and shrieks, or grotesque reproductions of familiar and simple airs. In Paris a curb has been put on this childish tendency to utilize the automobile as a means of scaring horses and pedestrians by making outlandish noises, and it is time that similar steps were taken in the larger cities in this country. There is no limit to the ingenuity of the inventor of these juvenile devices on a large scale, and, like a boy with a new whistle, many a driver takes fiendish delight in utilizing them to the utmost.

In the French capital the employment of such objectionable means of warning pedestrians and other traffic is placed under the ban altogether, and the weird shriek that the driver of a rapidly approaching car takes pleasure in producing in New York City would there subject him to immediate arrest. Parisian ears are no more sensitive than those of the dwellers in American cities, and the example of the French municipality in thus restraining what is nothing more or less than a childish practice is a commendable one that could well be followed here. Long-range warnings may be more or less of a necessity on country roads, but they certainly have no place in city driving, except when used for legitimate ends, as in the case of the fire department's cars. While the majority of autoists are common-sense individuals who do not indulge in the practice, there are sufficient numbers who thus make themselves offensive, to call attention to the matter, and it is to be hoped they will soon be suppressed.

## A. A. A. RE-ELECTS HOTCHKISS TO THE PRESIDENCY

**P**ERFECTLY content to leave in power an administration which, since February last, had increased the membership total from 8,000 to over 19,000, the Board of Directors of the American Automobile Association, made up of the chosen representatives of the various State bodies, on Friday last, reelected William H. Hotchkiss to the presidency; Lewis R. Speare, first vice-president; Asa Paine, second vice-president; Ira M. Cobe, third vice-president; George E. Farrington, treasurer, and F. H. Elliott, secretary.

The meeting was held at the association's headquarters, 437 Fifth avenue, and was attended by directors from Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Pennsylvania, District of Columbia, Ohio, Indiana, Illinois, Minnesota, and Florida. The greater part of the day was taken up with the reading of the annual reports, which were both exhaustive and interesting, and told of the great progress of the organization during the past nine months. The constitution having been changed so as to make the annual election come in November instead of January, and realizing that the present administration had not an opportunity of perpetuating its policies, there was no dissent against continuing the Hotchkiss-Elliott régime.

These chairmen have been asked to continue in office: Robert P. Hooper, Good Roads; Jefferson deMont Thompson, Racing; Charles Thaddeus Terry, Legislative; and F. B. Hower, Touring. A technical board and also a publications board will be added to the list of national committees. The executive committee will be increased to seventeen, including the chairmen of the boards.

Herewith are extracts from the various reports:

### From the Report of President W. H. Hotchkiss.

**Legislation.**—Comparatively few of the State legislatures meet this winter, but in those few efforts will be made either to revise existing laws, where the same are prejudiced or imperfect, or to pass the so-called uniform motor vehicle law where no laws now exist. Plans have already been made to this end, and the work can safely be left in the hands to which it has been committed. The legislative board will also make a determined effort to pass the Federal registration bill. Present indications point to the success of such efforts.

**Good Roads.**—The good roads movement is now national in its character. Whether much can be accomplished through congressional aid, I very much doubt. But our good roads board, through its State committees, has been able, and in the coming year ought to be able to accomplish much toward awakening interest in the subject and bringing motorists out in the open for it. After all, however, the success of this movement depends more upon the farmer and the grange organizations than upon us, and all our board can do is to assist in creating interest and co-operate with other bodies which are working to the same end.

**Racing.**—The characteristic feature of the motor racing situation of the past year was the large number of accidents incident to races on circular tracks. That the public demands the abolition, or, at least, the regulation of these races in such a way as to avoid accidents, will be conceded by everyone. The whole subject has, therefore, been turned over to a special committee on sanctions, which has already made certain suggestions looking to a union of this association with the various national bodies of manufacturers and dealers on some policy that will meet the views of the public.

There should, of course, be a Vanderbilt cup race next year, as well as a contest or contests between stock touring cars. Your executive committee already has under consideration several plans whereby both of these contests can be assured.

**Co-operation.**—A meeting recently held in New York seems to promise a better understanding between the association and the national bodies of manufacturers. These bodies have many interests in common. They have worked together too little in the past. If present plans are carried out, a basis for united action on all matters of common interest will be established, and much good cannot fail to inure to the association and its members.

### From Report of Chairman C. T. Terry, Legislative Board.

From its organization, your committee has considered of paramount importance in its work the enactment of a Federal law regulating the registration and identification of motor vehicles, and concurrently with that the enactment in the various States of the

Union of a uniform State motor vehicle law, covering not only the subject of registration and identification for the particular State in which such a bill should be enacted, but also all the other matters of regulation of motor vehicles which could not, at this time, at least, be incorporated in a Federal statute. To this end, as you are aware, your committee forthwith, upon its creation, began working upon the construction of a Federal automobile law and upon a uniform State motor vehicle act. The proposed fields of these two proposed statutes are entirely different, but they overlap at one point, namely, in the matter of registration and identification, and, of course, the purpose of the two bills in general is identical in this, that they both seek to obviate the very distressing and, as we think, unnecessary and unfair divergence between the provisions of law to which one may be subjected in interstate automobile travel.

During the coming winter your board will bend its energies to the enactment of these two bills, and urgently requests the active co-operation of the members of your board and all the influence which they can bring to bear to effect the purpose in hand, and to that end especially seek to acquaint the members of Congress

GOVERNOR HUGHES AND WILLIAM H. HOTCHKISS.

During the recent visit to Buffalo of the Governor of the State of New York he was the guest of William H. Hotchkiss, president of the American Automobile Association, and it naturally followed that the Thomas-Flyer of Mr. Hotchkiss was well employed, with its owner at the wheel.

throughout the country with the salient features of the proposed Federal bill, and to secure the support of the bill by such congressmen.

### From Report of Chairman R. P. Hooper, Good Roads Board.

Prior to the present year, the work of this board has been, of necessity, desultory. Conditions—the newness of the road problem, the difference from State to State in laws and methods, and the relatively small number of the association's State bodies—made productive work all but impossible. Early in 1907, however, the board was so organized as to properly perform its functions. This was accomplished by the appointment of State representatives, who, in turn, became the chairmen of State good roads committees, in the States where clubs have been or are about to be organized into State associations.

The good roads movement in the United States practically began with the introduction of the rubber tire, but active work on the main highways stretching through the States is coincident with the general use of the automobile. Since that time this work has progressed so rapidly that to-day it is of national importance. In its infancy it was easily handled by a few enthusiastic men, resident in the large cities, but, as the movement grew, it was quickly apparent that large things toward good roads could be accom-

plished only by a unity of associations in the various States, captained by a national association representative of all. No organization in the country is more interested in or better equipped for this work than the American Automobile Association. A movement is now on foot to centralize the activities of the different associations interested in good roads in a national organization, headed by the National Grange, and, acting under direction from the association's board of directors, the Good Roads Board is co-operating in such movement, and will recommend that the A. A. A. join such National Good Roads Association.

#### From Report of Chairman F. B. Hower, Touring Board.

It must be remembered that, until the present year, work of this board consisted only of the management of the annual tour, but now all is different. Our energetic and busy president laid out a line of work that has kept the office of the Touring Board bustling. General information, beneficial to tourists, has been pouring into the office from all sections of the country, and this information finally became so bulky that we found it necessary to devise some system for handling it. Large cabinets were built and are now in place. On cardboard, properly indexed, all routes, maps and information are transferred, and we are thus enabled to find immediately information asked for. It has been remarked that we should be able to furnish as reliable touring information as that supplied by the Automobile Club of Great Britain and Ireland. That criticism might hold true if this country did not cover vastly more territory than Great Britain.

The board so far this year has been of no expense to the association, and the annual tour resulted in a balance of \$2,020.10.

During the coming year special attention should be paid to hotel rates, garage rates, and data on improved roads. The automobilist seems to be a common prey to hotel proprietors and owners of garages, and the sooner this matter can be governed the better, and, with this object in view, the association should make an earnest effort to control the situation. This, we think, could be done to a great extent by correspondence. When the different hotels and

garages understand that this association numbers twenty thousand automobilists, and that they are kept posted on rates, its members will receive more courteous treatment.

#### In Report of Chairman J. D. Thompson, Racing Board.

Chairman Thompson recites the history of the conscientious and industrious efforts of the Racing Board to hold a 1907 race for the Vanderbilt Cup, telling why it was impossible to complete the Long Island Motor Parkway, and explaining why the efforts to hold the event in other States were either fruitless or unexpectedly interfered with. In conclusion, the chairman comments: "It is most unfortunate that the United States, which now leads the world in the manufacture of automobiles, should be the most backward in encouraging the industry, most reluctant to improve roads, and absolutely indifferent to our appeals for protecting a course on which to hold an international road race." Reference is made to the assistance given by the governments of France, Germany, Great Britain, Italy and Belgium in the holding of the annual automobile contests.

#### From the Report of Secretary F. H. Elliott.

The present membership of the A. A. A. includes 16 affiliated State associations, containing 120 clubs, with a total membership of 17,550; 15 unfederated clubs, with a membership of 1,035; and 621 individual members and three life members—a grand total of 19,209 on November 1. According to the association records on October 1, 1906, there were five State associations and 70 clubs, with an approximate membership of 8,857. There was practically no increase in membership between October 1 and February 1 when the new administration took office. The increase in the past nine months is 10,352 members.

## NEW YORK STATE BODY TO CONSIDER LEGISLATION

THE quarterly meeting of the New York State Automobile Association of the A. A. A. was held Friday, November 8, at A. A. A. headquarters in New York City, President Oliver A. Quayle presiding, with Secretary C. D. Hakes in attendance as usual. Directors were present from the Automobile Club of America, Automobile Club of Buffalo, Rochester Automobile Club, Olean Automobile Club, Albany Automobile Club, Schenectady Automobile Club, Long Island Automobile Club, and Richmond County Automobile Club. The present membership of the State association is over 5,000 and contains 31 clubs.

It was decided to appoint a special committee to consider

the matter of legislation, the president being empowered to make appointments at an early date. This committee will report its recommendations to the Board of Directors previous to the convening of the next session of the New York State Legislature.

The State association decided to issue a Year Book and to supply a copy to each member of every club in the association, as well as to the individual members.

The good roads tour, which will be participated in by prominent members of the New York State Legislature, will take place during the present month.

#### PENNSYLVANIA FEDERATION VERY ACTIVE.

PHILADELPHIA, Nov. 11.—A meeting of the executive committee of the Pennsylvania Motor Federation, composed of the officers and chairmen of the several standing committees, was held at the automobile Club of Philadelphia, November 6.

The treasurer's report showed a healthy financial condition, the membership now exceeding 1,800. The Bangor Automobile Club, with a membership of 48, was admitted to membership, and a notification was received from the Motor Club of Harrisburg that its formal application would be forwarded.

Reports received from the legislative and good roads committees showed encouraging activity on their part. Many of the clubs throughout the State have actively taken up the work of inducing, or, if persuasion fails, of compelling road supervisors to observe too much neglected provisions of the road laws of Pennsylvania, the first requiring the erection and maintenance of finger signs at all cross roads, and the other that once a month during the summer all loose stones must be removed from township roads.

As the legislature of Pennsylvania does not meet until the fall of 1908, little can be done by the Legislative Committee.

#### OHIO ASSOCIATION WANTS NEW LAW.

CLEVELAND, Nov. 11.—The highways committee of the Ohio State Automobile Association met in Cleveland recently and discussed a plan for introducing automobile legislation before the coming session of the Ohio legislature this winter. There is a growing desire among the majority of automobilists for a State license law requiring the issuing of all car numbers and licenses by the State, as is done in other States. It is the aim to have the fees and fines from the violations of the State automobile laws go to the State road fund, which has been entirely inadequate heretofore to accomplish much good. The automobilists of this State are not only becoming disgruntled at the lack of good roads work on the part of the State, but the system which allows villages and towns to make their own speed ordinances and levy tribute for alleged violations of unknown regulations is one of the most discouraging features of touring in this State.

The Ohio State Automobile Association has been making good gains in membership during the past few months, and it is believed that it is now strong enough to make an effective campaign during the coming session of the legislature.

ROBERT ESNAULT-PELTERIE'S ORIGINAL BIRD-LIKE FLYING MACHINE SUCCESSFUL IN SKIMMING OVER GROUND.

## FARMAN DESCRIBES CIRCLE WITH AEROPLANE

PARIS, Nov. 11.—Skeptics who insinuated that aeroplane flights were nothing more than jumps are effectively silenced by the latest performance of Henry Farman and his aeroplane built by the Voisin Frères. Farman has so often flown over the military ground at Issy-les-Moulineaux in its greatest length for anyone to doubt his ability to fly in a straight line.

On Saturday afternoon Farman made the most brilliant demonstration of the season by flying a kilometer in a circle. Starting from the lower end of the ground near the river, the machine ran a few yards on its four wheels, then gradually rose into the air. It was obvious that Farman had complete control of his heavier-than-air flyer, for under the influence of the rudder it was gradually brought round with but a slight heeling towards the ground. At the top of the field the turning movement was completed, and the nose of the machine towards the starting point, a straight run was made for home. The kilometer circle had been covered for the first time in 1:14.

A wave of enthusiasm spread over the ground as Farman descended from his machine, the spectators realizing that the circular flight was a complete triumph for the heavier-than-air theory. Ernest Archdeacon, who with M. Deutsch has put up a prize of \$10,000 for the first flight of one kilometer in a closed circle, rushed forward to congratulate Farman on his success. Although the aeronaut will not immediately pocket the 50,000 francs as the result of his flight, it is unanimously admitted that he fulfilled all practical conditions and that the performance can be repeated at any time. The regulations for the Deutsche-Archdeacon prize declare that notice of an attempted flight must be given the Aero Club of France several hours in advance, that the flight must be observed by a deputation and that the distance must be officially measured. Henry Farman had given no notice of his intention to try for the prize, his afternoon's work being merely an ordinary trial spin; thus he is not entitled to the cash.

The world's most successful aeroplane has never paid much heed to official records, his most important flights having all been done in private practice spins visible to the world. In conversation recently, he declared that the most successful feature of the machine, in his opinion, was that in every case he had been able to come to earth without any breakage. "Even now," said Farman, "leaving the ground is not an easy matter, and flying is much more difficult. In all flights up to the present I either rise too high, and my motor is not able to do the work of lifting a

machine weighing over one thousand pounds, or a wrong movement is given to the equilibrator and I am brought to the ground. A tremendous amount of thought is involved in even a short flight, for I have to look after the rudder at the rear, the equilibrator, the ignition, throttle, gasoline and water pressure, besides keeping an eye on the crowd."

### Another Aeroplane of Which Much Is Expected.

Public interest has been centered on the aeroplane of M. Esnault-Pelterie, recently successful in covering a distance of more than one hundred yards on the inventor's own grounds near Versailles. The bird-shaped machine has a central body carrying the motor driving a four-blade propeller forward, and a couple of wings, each one being hinged to the body and designed to pivot independently. The rear plane, forming a tail, is also arranged to be either raised or lowered through the mechanism of two levers. The motor is also a special design by Robert Esnault-Pelterie, and comprises four cylinders staggered round a circular crankcase. It develops 22 horsepower. Total weight of the machine is 500 pounds.

### SKY PILOT BRIGADE FOR BOSTONIANS.

BOSTON, MASS., Nov. 12.—New England will soon learn to fly, unless the plans of Charles J. Glidden and the handful of enthusiasts associated with him go seriously astray. At the Hotel Touraine, this week the New England Aero Club was formally ushered into existence under the care of Charles J. Glidden, George E. McQuesten and Alfred R. Shrigley, all prominent members of the Massachusetts Automobile Club. A further meeting was arranged for November 21, which is the 204th anniversary of the first balloon ascension in New England. The new club, which will occupy itself more with the sporting side than the scientific features of aeronautics, hopes to establish a permanent ascension station.

### BELL FLYING MACHINE TRIALS SOON.

HALIFAX, N. S., Nov. 11.—Professor Alexander Graham Bell expects to start the preliminary tests of a new airship in a few days. Initial trials will be made by towing the machine without operator or motor, their weight being provided for by ballast. When these are successful, an operator will be allowed to take his place in the flying machine.

**SUCCESSFUL TESTS WITH DENATURED ALCOHOL.**

During the past week at the New York School of Automobile Engineers, 146 West Fifty-sixth street, New York City, there have been held some unusually successful tests with denatured alcohol as a fuel. Roger B. Whitman, technical director of the school, and his assistant, Julius C. Liebhardt, have been investigating the matter for some time and their experiments have proved so successful that a general invitation was issued to those interested to call at the school during the week of the Garden show. The fuel employed was commercial 94 per cent. alcohol mixed with 10 per cent. benzine and 2 per cent. wood alcohol, according to the government formula, and cost 30 cents per gallon. Apart from the fact that the carbureter was raised to the level of the inlet valves and the intake manifold made as short as possible, no special preparations were made. The carbureter was a stock Schebler of the 1907 pattern and the fuel was fed by gravity. In an old two-cylinder, 5-horsepower Daimler engine of the automatic inlet-valve type, which had been presented to the school by the makers merely as an alternative to throwing it on the scrap heap, the alcohol fuel permitted of instantaneous starting with everything cold, and although the compression was only 45 pounds, the old motor showed a brake output greater than its original rating. The consumption was naturally greater than with gasoline, but neither the facility of starting nor the power developed could be improved upon, and, according to Mr. Liebhardt, it has been found possible to reduce the consumption to as low as 1.4 pints of denatured alcohol per horsepower hour.

The second test was even more interesting and consisted of starting a four-cylinder Mercedes motor of the pattern of 1903, equipped only with a low-tension magneto for ignition, on the same fuel. Flooding the carbureter in a manner that would prevent starting on gasoline owing to the richness of the mixture, and giving the motor five or six brisk turns in order to accelerate the magneto, never failed to produce a start with everything dead cold. While running, the entire inlet manifold drops in temperature until it practically reaches the freezing point, owing to the rapid evaporation of the alcohol. It is the intention of the school in the near future to run one of its instruction cars on alcohol altogether, and the data thus obtainable should prove of interest. Joseph Tracy, whose experiments with alcohol last January will be recalled, was an interested visitor, but preferred not to commit himself to any opinion regarding the unusually successful outcome of the experiments, choosing to take the position of an observer only on this occasion.

**AN INTERPRETATION OF THE INDIANA LAW.**

INDIANAPOLIS, IND., Nov. 11.—The Indiana Supreme Court last week held that the recently enacted automobile law requiring automobile drivers to stop on signal from occupants of a buggy, even if the signal is not given by the driver, is valid.

For several months the case, brought from the De Kalb County Circuit Court, has been waiting a decision from the upper court, and in the meantime much controversy as to its legality has been aroused. An affidavit was originally filed against Samuel Goodwin by Josie and Rose Case, but it was quashed on the plea that the signal to stop had not been given by the driver of the horse.

"Driving in its popular sense," declared Judge Hadley in his decision, "means more than mere managing or directing a horse. It has, at least, a dual signification. When it is said that a party goes out 'driving' or 'boating' it is not usually understood that each member of the party performs the physical act of driving the horse, or of rowing the boat. . . . Even a strict construction would require us to hold that any occupant of the vehicle may give the signal."

This is the first time that the law has ever been tested in the State, authorities fearing it would not hold good in the courts. It is probable that from now on special effort will be made to enforce it.

**TEMPORARY RECEIVER FOR ROYAL COMPANY.**

CLEVELAND, Nov. 13.—The Superior Savings and Trust Company was yesterday afternoon appointed receiver by the United States Circuit Court for the Royal Motor Company, of this city, on proceedings brought by E. W. Cottrell, of Detroit, and W. K. Cochrane, of Chicago, stockholders and creditors. The action was brought to tide over embarrassment due to the money stringency.

The company is four years old, and recently moved into a large new plant, where it employed 400 men. Its business has increased in three years from \$90,000 to \$1,500,000. President Shurmer of the company says that the corporation is abundantly solvent and that the recent financial statement showed assets of \$650,000 in excess of liabilities. Large contracts on hand for next season necessitated heavy loans, and recent calls make it impossible for the company to meet maturing obligations. F. A. Scott, treasurer of the bank mentioned above, which has been appointed receiver, says there is no reason for alarm as to the outcome, as assets appear to be good, and the embarrassment will be only temporary.

**CONDITION OF POPE AFFAIRS AT TOLEDO.**

TOLEDO, O., Nov. 10.—George A. Yule, of Kenosha, Wis., has been appointed as an additional receiver to serve with A. L. Pope in the settlement of the affairs of the Pope Motor Car Company. The appointment was made on the petition of certain creditors, and Mr. Yule is now in this city for the purpose of making an inventory of the assets of the local plant.

In this connection announcement has just been made of a probable sale of the Toledo plant to a number of New York men, and A. E. Schaaf, general manager of the plant, is now in that city in the interests of the sale. Speaking of the sale, Mr. Yule said that had it not been for the financial flurry of a few days ago the sale would in all probability have been consummated prior to this, but that a final sale is anticipated shortly.

While Mr. Yule will not confirm the story, it is said on good authority that the prospective purchasers plan to spend several hundred thousand dollars in enlarging the plant and in making it one of the finest and most complete automobile factories in the United States.

**A. E. Schaaf Has Been Requested to Resign.**

TOLEDO, O., Nov. 11.—A despatch to the New York *Times* contains the following information: It was learned to-day that Albert E. Schaaf, who has been manager of the Toledo factory of the Pope Motor Car Company for a number of years, has been requested to resign by Albert L. Pope, one of the receivers of all the Pope factories. Harold Pope is now in charge.

Schaaf's management of the plant, so far as known, has been entirely satisfactory, yet the receiver has informed him that he is no longer wanted in a managerial capacity by the Popes. As George Yule, of Kenosha, who was recently appointed a co-receiver of the Pope factories by the United States courts in a number of districts, was not consulted as to the resignation of Schaaf, and therefore was not accorded an opportunity of either confirming or refusing to concur in it, there are likely to be difficulties before the matter is settled. Schaaf will vigorously contest the discharge.

**EDWARDS TO HEAD LONG ISLAND A. C.**

BROOKLYN, N. Y., Nov. 11.—Charles Jerome Edwards, the well-known automobilist and aeronaut, has been nominated for the office of president for the coming year, by the nominating committee of the Long Island Automobile Club. Mr. Edwards is an autoist of considerable experience and well liked, so that the nomination met with general approval on the part of the members. Owing to the progressive policy of the club, its membership is rapidly increasing, the interesting investigations and reports of the technical and other committees being largely responsible.

## SOME FACTS CONCERNING FORTHCOMING CHICAGO SHOW

CHICAGO, Nov. 11.—In keeping with its reputation for doing things on a big scale, Chicago is to have the biggest automobile show of the year, and the only national show, as the Windy City is the only place in which the makers of the opposing camps come together to exhibit their cars under the same roof. As compared with the combined total of 110 exhibitors of complete cars at the two recent New York shows, the Chicago list already shows a total of 117, and nothing but a lack of space prevents the addition of some twenty odd, as there are more than that number on the waiting list, and at least half a dozen of these are said to be of considerable importance. The total floor space to be occupied will be something like 110,000 square feet. Owing to the inability of the management to comply with all the demands for space, for the first time in the history of automobile shows, the ban on subletting space has been removed, and it is thought that the 180 accessory exhibits catalogued on the official list will be augmented by some 50 or more whose names will not appear upon the latter.

Where the decorations are concerned, Manager Miles has always made the Chicago show distinctive by giving it an automobile atmosphere, so to speak, and this will be the case with the present show, which opens on November 30. The chief features of the ornamentation will consist of 112 oil paintings by Hardsy Maratta, all of them representing automobile scenes, the latter being distinguished by the fact that the car depicted by each painting will be of the make shown in the exhibit beneath it. The entire gallery front will also be covered with paintings of

automobile scenes made from photographs taken in a dozen different countries. In all there will be nearly 9,000 square feet of oil paintings, 20,000 feet of papier maché representations of automobile events, 150 of the Mercury automobile plaques which have become the distinctive shield of the Chicago show, 150 new figures adorning the pillars in front of the spaces, more than a mile of signs, more than 100,000 square feet of ornamental work in the ceilings of the buildings, 20,000 feet of paneled wall covering, 110,000 square feet of carpeting and three or four tons of miscellaneous staff ornaments.

The commercial vehicle section of the show, which will be housed in the Seventh Regiment Armory, formerly known as Tattersall's, has assumed quite unexpected proportions, some of the most recent additions being the E. R. Thomas Company's motor cabs, the wagons of the Pittsburg Motor Vehicle Company, and the Alden Sampson gas-electric road train, consisting of a 10,000-pound tractor and two 7,000-pound trailers. There is now a total of twenty-seven automobile exhibits in this section. Owing to the purely commercial aspect of this part of the show, admission will be largely by invitation, season tickets being presented to traction experts, buyers and other officers of companies interested in transportation problems. Invitations have been issued in liberal quantities to all the exhibitors to be given out in their own names to prospective customers, so that in addition to being the first representative showing of vehicles of this class, it is confidently anticipated that it will bring together the first large gathering of men interested in autos.

## SAN FRANCISCO'S SHOW TO BE NOTABLE EVENT

SAN FRANCISCO, Nov. 1.—As a result of the success of last year's automobile show the Dealers' Association of California have determined upon a second exhibition. The Coliseum, which is one of the largest buildings in the United States, has again been chosen to house the display. The date has been fixed at the second week in December, and at a recent meeting of the Dealers' Association a committee composed of George Middleton, of the Middleton Motor Car Company; Herbert Choynski, of the General Motor Car Company, and J. A. Marsh, of the Mobile Carriage Company, were selected to handle the show. N. R. Cooper, who had charge of the show last year, has again been engaged to manage the affair this season. The Coliseum covers almost an entire block, and is situated directly opposite to the main entrance to Golden Gate Park. Directly to the south of the Coliseum, and only two or three blocks distant, is one of the steepest hills in San Francisco, which is also a city park. With this incline for demonstration of hill-climbing ability and the smooth roads of the park accessible for purposes of exhibiting the

other faculties of an automobile, it is not necessary for the San Francisco dealer to take long runs into the country to show every phase or every talking part of his car.

In addition to this the Coliseum is almost entirely on the ground floor, and has actually more ground floor space than has Madison Square Garden in New York. As snow is an unknown thing in San Francisco, the park will be green the year round, and the roads in Golden Gate Park are always in perfect condition. Last year San Francisco's show housed eighty-four different and distinct exhibits, and showed over one hundred and fifty different makes and models of automobiles. This year the exhibits will be even greater in number.

Decorations, out of courtesy to the Automobile Club of California, will be green and yellow, the official colors of this club, and will consist largely of green shrubs and palms, which will be secured from Golden Gate Park. As in last year's show, uniformity of exhibits, decorations and signs will be preserved throughout the entire pavilion, and simplicity will also be sought.

### THE PROPOSED WESTCHESTER CHASSIS RACE.

The project of holding a stock chassis race next April in Westchester County has been receiving attention of late. An inspection of the proposed course of some forty-two miles in extent, and located about twenty-five miles from New York City, was made on Monday last by interested parties, including officials of Westchester County. The route, besides passing through two villages where controls would have to be established, runs through six townships, and the consents of all of the town boards would have to be obtained. According to the *New York Herald*: "Robert Lee Morrell, who is chairman of the general committee, is engaged in waking up the various committees in charge of the details of the race." T. F. Moore, the secretary of the committee, is optimistic concerning the Briarcliff Manor event.

### ANNUAL SHOW DINNER OF WHITE COMPANY.

At the Waldorf-Astoria on Wednesday night of last week, the White Company gave its usual dinner to the White agents in attendance at the show, and also invited newspaper men from New York and other cities. Windsor T. White was the toastmaster of the evening, one of the incidents of which was the presentation of a gold watch and chain to Hal Sheridan, driver of the White runabout which won the Hower trophy in the A. A. A. tour.

The function was well arranged and neatly carried out. Walter White, who sailed on Saturday to look after White interests abroad, outlined the successful policy of the company from its beginning. George W. Bennet, manager of the New York City branch, issued the invitations in behalf of the company. The Hower trophy was prominently in evidence.

A SIMPLEX WITH BRIDGEPORT VEHICLE BODY AND WINDSHIELD.

### BRIDGEPORT CO. TO MAKE RENAULT BODIES.

BRIDGEPORT, CONN., Nov. 11.—Interest attaches to the announcement that a contract has just been closed by President Harry D. Miller, of the Bridgeport Vehicle Company, of this city, with the Renault Frères Selling Agency, which handles Renault cars in the United States, whereby the Bridgeport Vehicle Company will henceforth make the bodies for the Renault chassis imported here. These bodies will be of the standard touring, limousine and landaulet types and will be fitted to all Renault cars which are sold complete by the makers.

Some samples of the Bridgeport Company's production were to be seen on the Simplex cars which were exhibited in the basement of the Garden show during the past week in New York City, one of the cars being shown by the accompanying photograph. Everything on this car above the frame is the work of the makers in question, and particular attention is called to the windshield. This is of plate glass in a mahogany frame and is supported by adjustable arms which slide on the permanent stays, being readily adjusted at any position by means of set screws.

### SUCCESSFUL END OF ATWATER-KENT TEST.

Considerable interest attached to the breaking of the seal of the Atwater-Kent apparatus which has been run in conjunction with a Jones speedometer-odometer during the course of the two recent shows in order to demonstrate the high mileage obtainable from dry cells by its use. An Atwater-Kent timer taking current from six dry cells and connected to four spark plugs was sealed in a glass case together with the speedometer on October 25. The connection with the latter was equivalent to being placed on a car having 34-inch wheels and a gear ratio of 3 to 1, the average speed maintained being about twenty-five miles an hour. The case was officially sealed by Albert W. Jacobi, superintendent of the machine shop of the Automobile Club of America. The sparking gap was made 7-64 inch in order to give the equivalent of sparking under compression. At the conclusion of the test, the odometer reading was 4,249.3 miles, while the cells were still good for further service, as they showed an average of 6.5 amperes. No adjustments of any kind were found necessary on the timer.

### HOW THE AUTO MET THE EMERGENCY.

LOS ANGELES, CAL., Nov. 9.—Bumping over mountain trails at an average speed of twenty miles an hour, and plowing through 100 miles of desert sand, Burt H. Paul, with three companions, reached Long Beach last night from Avawatz, a mining camp 270 miles away. The trip was made in thirteen hours, a record-breaking performance. The big 35-horsepower Mitchell behaved well and needed scarcely any attention during the entire journey.

Important business called the officers of the Avawatz Development Company to the mines in a hurry. Paul undertook to drive

them. It meant a dreary stage ride if they tried to reach the mines other than in an auto. The trio accepted. Frederick Heath, Joseph Pitts and Edward Martin made the journey with Paul. All would have been well had they not lost their way while chugging across the desert.

The party came to a place where two roads met, chose the wrong path, and soon found themselves in a trackless waste. Miles of sagebrush were passed, and they crashed through cactus, until they finally had to admit they were lost. Hours were spent running aimlessly over the desert sands. Toward night a lone rider pointed out the right path and Daggett was reached in time for supper. This costly experience made the autoists wary during the remainder of the journey, and they were satisfied to stay on the main road, eschewing all short cuts.

### OLDS HAS NO MISGIVINGS FOR THE INDUSTRY.

"I have not the least misgiving as to what bearing the present financial disturbance shall have upon our business for 1908," says R. E. Olds, president of the Reo Motor Car Company.

"The good sense of the American people and their matchless confidence in the nation, as a whole, have always won out in great crises, and I believe that they will readily solve the present difficulty which seems to be but temporary. The prosperous condition of every legitimate business throughout our land indicates another high water mark of prosperity during 1908."

### KANSAS MAKING PLANS FOR AUTO TOLL ROADS.

TOPEKA, KAN., Nov. 11.—J. R. Drilling, a resident of Garden City, Kan., is now busy with the organization of a company for the construction of special automobile roads in the western half of this State. The plans call for roads from Garden City east to Hutchinson, Great Bend, Wichita, or other important points, and west to the State line. The roads are to be exclusively for automobiles and toll will be charged according to distance run.

### MAXWELL ON THE AUTO TRADE OUTLOOK.

"If the pessimists who predicted a falling off in the automobile business on account of the recent slump in the money market had visited our booth at the automobile show in the Grand Central Palace," said J. D. Maxwell, vice-president of the Maxwell-Briscoe Motor Company, "they would have found that their ideas on the subject are entirely wrong. This is proved by the fact that during show week our receipts at the Grand Central Palace, in the shape of deposits, averaged \$20,000 per day. Furthermore, the fact that we have increased our orders for raw material by fifty per cent. ought to have a tendency toward changing the opinions of pessimists regarding the automobile business."

J. D. MAXWELL AND BEN. BRISCOE IN THE LATEST MAXWELL CAR.

## BRIEF ITEMS OF NEWS AND TRADE MISCELLANEA

The Royal Motor Car Company, capitalized at \$100,000, with \$51,000 paid in, has been organized at Detroit, to manufacture motor driven vehicles. Paul Arthur as trustee, and Robert Webster are the principal stockholders.

The Seitz Automobile and Transmission Company, composed of capitalists from Monroe, Mich., who own patents covering a transmission for autos and other machinery, has decided to locate in Detroit. The company is capitalized at \$50,000, of which \$20,000 is paid in.

The spark coil and plug department of the Fischer Special Manufacturing Company, Cincinnati, O., having assumed such large proportions, it has been deemed advisable by this firm to separate it entirely from its other specialty business, and for this purpose the Fischer Ignition Company has been formed.

The Hartford Suspension Company has been elected to active membership in the New York Automobile Trade Association the company having been an associate member for some time. The Mitchell Motor Car Company and the Carl H. Page & Company are also new members of the association, Mr. Page being added to the directorate.

R. M. Owen & Company have just been advised by James L. Farmer, secretary of the jury of awards of the Jamestown Exposition, that a gold medal was awarded Reo No. 33 for the 500-mile non-stop dash which it made from New York to Jamestown immediately after finishing the 1907 Glidden tour with a perfect score. Mr. Farmer further states that a replica in bronze of the medal will accompany the award diploma.

A petition in bankruptcy has just been filed against the Da-An-Nite Auto Supply Company of New York City by the following creditors: The B. F. Goodrich Company, \$2,898; Harburg Tire Company, \$1,703, and the Diamond Rubber Company, \$1,244, the petition being based on the fact that the company admitted its insolvency in writing on November 4 last, as well as its willingness to be adjudicated a bankrupt. Frank J. Wallace is president of the company, which was incorporated on December 3, 1906, with a capital of \$20,000.

The Chase Motor Truck Company, Syracuse, N. Y., has acquired a plant for the enlarging of its business. The plant was formerly occupied by the Sweet Steel Company, is located at 310-34 South West street, in that city, and covers 58,000 square feet. Besides the office building on West street, there is a four-story machine shop, a one-story erecting shop, and a one-story pleasure car department. The manufacture of the Chase two-cycle air-cooled commercial cars will be pushed with the enlarged facilities. The pleasure car department will continue the sale of the Ford line.

The White Company, Cleveland, O., makers of White steam cars, has issued a new route book, the fifth in the series issued by the company. The new book gives detailed road directions for over 1,500 miles of the main highways, suitable for tourists in New York State, and in the province of Quebec. The routes given include those in both directions between New York and Albany and in both directions between Al-

bany and Buffalo. In addition, directions are given for the route northward from Albany to Saratoga, and thence by way of Elizabethtown, Plattsburgh and Rouses Point to Montreal. From the latter city the route is given along the north bank of the St. Lawrence to Quebec. Still another route is that by way of Tuxedo and Central Valley to Newburgh. The new route book, like the four numbers which have preceded it, is profusely illustrated.

Individual instruction for owners and chauffeurs in operating automobiles on the crowded streets of New York is the latest improvement adopted by one of the schools for training chauffeurs and owners to operate and care for their cars. To carry on this work of giving every student a full training in operating a car in which he is alone with the instructor, this school, operated by the West Side Y. M. C. A. of New York, has been compelled to add the fifteenth car to its experimental and practical equipment. Under the plan at the Y. M. C. A. school, the student, with no one but his teacher, takes the car out, runs it through the streets and brings it back. Various types of cars are used at the different road lessons, and the practice is so planned that every student has had ample personal experience in handling wheel and throttle under all sorts of difficult driving conditions. The individual plan also gives the instructor full opportunity to test the pupil chauffeur on the rules and laws of the road. It is the rule of the school to "queer" cars in every possible way, and then to make the student diagnose the trouble and remedy it. Students also take cars to pieces and then rebuild them, and in this way put into actual practice in the work shops the information given at the theoretical lectures.

### RECENT TRADE CHANGES.

I. C. Kirkham, Brooklyn and Long Island distributor for the Maxwell, is preparing to remove from his present cramped quarters at Bedford avenue and Fulton street, to his new and commodious garage and salesrooms, on Bedford avenue, corner Clifton place.

### NEW AGENCIES ESTABLISHED.

Charles E. Miller, the well known New York auto supply dealer, has opened a Brooklyn branch at 1932 Bedford avenue, corner of St. Mark's place.

The Times Square Automobile Company, of New York City, has opened a branch at 309-311 Michigan avenue, Chicago, which will be operated on the same principle as the New York house. Only first-class second-hand automobiles will be carried.

Joseph D. Rourk, for the past two years identified with the Cadillac sub-agency in Brooklyn, N. Y., has secured sole Long Island rights for the sale of Cadillacs, and will continue his headquarters at 1001-3 Bedford avenue. In the past the Brooklyn agency has been a branch of the New York distributors, but will be entirely independent in the future.

### PERSONAL TRADE MENTION.

Louis Caswell, well known in the automobile trade, has been appointed sales manager of the Moon Motor Car Company, of St. Louis.

W. H. Dougherty, representative of the Fisk Rubber Company in the Central West, will in the future represent that company in his old territory, New York State.

F. B. Cole, for the past three years foreman of the repair shop of the H. H. Franklin Mfg. Co., Syracuse, N. Y., has accepted a position with the Boyer Motor Car Company, San Francisco.

W. V. H. MacEvoy, formerly sales manager of the C. G. V. Import Company, has joined the sales forces of Archer & Company, sole American concessionaire for the Hotchkiss car, and agent for New York City and surrounding territory, for the Pennsylvania.

Charles C. Craig, formerly sales manager of the Harrison Motor Company, Grand Rapids, Mich., has been appointed sales manager for the Model Automobile Company, Peru, Ind. Mr. Craig is well and favorably known in the trade, and his many friends will be pleased to learn of his new connection.

### THE BANKRUPTCY LIST.

KANSAS CITY, Mo., Nov. 9.—The Kansas City Motor Car Company, makers of the Phoenix truck, filed to-day a petition in involuntary bankruptcy. It is signed by F. E. Wear, president, and principal creditor; the William C. Johnson & Sons Machinery Company, of St. Louis, and G. S. Blakeslee, of Kansas City. Liabilities are estimated at \$300,000 and assets at \$150,000. The cause of the petition is given as the present financial stringency, and a statement is made that the company will try to resume business.

BOSTON, Nov. 12.—Howard E. Whiting, automobile dealer of Cambridge, to-day filed a bankruptcy petition. Liabilities, \$11,563; assets, \$7,926.

### NEW TRADE PUBLICATIONS.

Morris metallic packing is the subject of a small booklet from H. W. Johnson-Manville Company, William street, New York. In addition to the ordinary grades, the packing is made for such special conditions as steam turbines, air, hydraulic, gas and ammonia service.

To present the Tincher 1908 model to the motoring world its manufacturers, the Tincher Motor Car Company, of South Bend, Ind., have issued an elegant illustrated catalogue. The new model is dealt with very briefly, but is shown to the best advantage by numerous and excellent half-toné illustrations.

Some information on the principles on which the Warner auto-meter works is contained in a booklet from the Warner Instrument Company, of Beloit, Wis. The Warner combined auto-meter and clock is also described and illustrated, and the intermediate gear by means of which two instruments can be fitted.

Having produced a superior type of buggy-about, which they have designated the autorunabout, the Schacht Manufacturing Company, of Cincinnati, O., has issued an elegant catalogue descriptive of their output. Those interested will be fully able to appreciate the qualities of the autorunabout by a perusal of the text and an examination of the many illustrations.

INFORMATION FOR AUTO USERS

**Weed Tire Chain Adjusters.**—In order to do away with the clanking commonly heard from cars equipped with Weed chain grips, the makers, the Weed Chain Tire Grip Company, 28 Moore street, New York, have recently brought out an improvement in the shape of an automatic adjuster. This consists of four springs attached at equidistant points round the wheel to the chain

WEED ADJUSTER IN POSITION.

grips, and at the other end to four points on a piece of chain which thus assumes a square outline round the hub of the wheel, as shown by the accompanying illustration. This not only does away with the objectionable noise, but also serves as an automatic "take-up," without at the same time preventing the chain grip from creeping round the tire. Thus the adjuster keeps the chain grips sufficiently taut to prevent rattling or striking the mudguards, and also to take up for wear, but allows sufficient freedom for this progressive action, which is essential to the life of the tire.

**Neverout Double Focus Searchlight.**—Ever since acetylene headlights have been employed on automobiles, drivers have felt the necessity of having a light which would not only reveal obstructions sufficiently distant to make it possible to pull up in time when going at speed, but also to show the nature of the surface of the road immediately in front of the car. To meet this demand, the Rose Manufacturing Company, 925 Arch Street, Philadelphia, Pa., have brought out their new Neverout double-

PRINCIPLE OF DOUBLE FOCUS LIGHT.

focus searchlight, the principle of which is illustrated by the accompanying cut. In addition to throwing a strong ray ahead and lighting the road-surface and side, these searchlights are made extremely powerful. They are used in connection with the patent Invertible Safety Gas Producer made by the same concern, and which embodies numerous features of merit exclusive in this device, on which, as its name indicates, the

manufacturers hold patents. It is made in either single or double cylinder types, the latter being recommended for use with the new double-focus headlight.

**Wico Spark Plugs.**—Under the title of "Wico," the Witherbee Igniter Company, 541 West Forty-third street, New York City, has just brought out a new type of spark plug for which much is claimed. This new plug is illustrated by the accompanying cut. B is the main carrier for the porcelain, A the packing gland, D the main shell into which the porcelain screws, and C the lock nut for the porcelain carrier B. One of its chief features of distinction is the fact that it is equipped with a micrometer adjustment, so that the gap can be set to .001 inch, to conform to the requirements of any compression, or to a magneto or battery system of ignition. This adjustment is accomplished by loosening the nut C and raising or lowering the

CROSS SECTION WICO SPARK PLUG.

porcelain carrier B. By observing the location of the latter before starting, turning 1-6 of a revolution either way, gives a difference of .001 inch in the width of the sparking gap. When correctly adjusted, the nut C is again locked. By loosening C the porcelain may also be withdrawn for cleaning, making the operation a very simple one. The makers guarantee the porcelain not to break or crack under the most intense heat, while the ends of the electrodes are so formed that they act as a siphon cleaner, at the same time providing a large and efficient sparking surface.

**Archer Gasoline Tanks.**—After a long series of tests showing conclusively that its use prevents all loss by evaporation, as well as any trouble from water or dirt in the gasoline, the Archer Tank Company, 76 West street, Rutland, Vt., are placing their new system of gasoline storage on the market. The apparatus is of the simplest description, consisting only of valves and piping understood by every mechanic and plumber, all pumps and other complications being avoided. To draw off gasoline it is only necessary to open a valve and close it when through. The system acts on the well-known principle of water displacement, the gasoline being drawn from the top of the tank, while all water and sediment remain at the bottom and cannot possibly escape through the gasoline valve. The tank is carefully made of heavy boiler steel, riveted and caulked, and is buried in the ground for safety and con-

venience. The makers have tested their tanks thousands of times to convince skeptical customers, but the chamois has never shown a trace of water.

**Travers Blowout Patches.**—Legion hardly suffices to describe the number of devices evolved to enable the autoist to make good the unexpected rim cut or blowout, all of which, however, seem to lack in some particular essential or other. According to the makers, the Travers Patent Blowout Patch Company, Broadway and Thirty-second street, New York City, this is not the case with their invention. It is built up of rubber and fabric, the same as a shoe, and has a brass flange on the side which locks to the rim and effectively prevents creeping. The patch fits inside the shoe and between the latter and the inner tube and keeps its position as long as the shoe lasts, no cement, straps, lacing or bolts being necessary to put it in place. While protecting the inner tube, it is also protected by the shoe.

**Bemus Double Ball Contact Timer.**—The T. Alton Bemus Company, 358 Atlantic avenue, Boston, Mass., have perfected their new ball-bearing timer to a point where they are willing to guarantee it to be good for 60,000 miles running, provided it is kept well lubricated and the points of contact, which are 3-8-inch steel balls that may be renewed anywhere at a nominal expense, replaced every 5,000 miles. The ball-bearing is of the simplest construction and is readily adjustable. The ball-races are made larger than usual and each contains 21 3-16-inch balls, thus insuring long life and a continued rigid bearing, an arrangement that makes it possible to guarantee accurate timing for a tremendous mileage. Felt and fiber washers are employed to ren-

SECTION VIEWS NEW BEMUS TIMER.

der the timer oil-tight, as well as dust-proof. The construction of the sockets carrying both the central and outside contacts has been altered, the center contact being brought nearer the axis and the outside contacts extended further in through the insulation, so that any specified number of degrees of contact may be obtained.

# THE AUTOMOBILE

VOL. XVII

NEW YORK—THURSDAY, NOVEMBER 21, 1907—CHICAGO

No. 21

## Twice Round the Clock on the Open Road

BY W. F. BRADLEY

SEVEN silver cups are needed in New Jersey. Those entitled to them are: J. B. Ryall (Matheson), R. G. Kelsey (Haynes), Ralph Owen (Oldsmobile), R. A. Green (Locomobile), A. T. Purcell (Ford), S. D. Atkinson (Franklin), and Montague Roberts (Thomas Flyer), all of whom finished the twenty-four hour endurance run organized by the New Jersey Automobile and Motor Club without a single lost point. Seven others completed the day-

and-night run, but failed to meet all the requirements of the competition, and the same number were obliged to abandon the contest at different stages through accident or weakness.

Promptly at 2 o'clock, Friday, November 15, Mayor Hurling, of Newark, fired the starting pistol, and J. B. Ryall, with a 1908 Matheson, so recently out of the factory that its paint work had not been completed, responded by going over the line with a full load of passengers. R. G. Kelsey followed one minute later on a four-seater Haynes runabout, racy-looking with its short exhaust pipes projecting through the bonnet, and its monster gasoline tank in the rear. Ralph Owen piloted No. 3 Oldsmobile, and J. P. Hopson took charge of No. 4 Olds "Mudlark" of Florida fame. Three Maxwells, piloted respectively by Dan McCormick, D. Nichols, and Charles Fleming, went away as the word was given, and were followed by Mrs. M. H. Rickey, the only lady driver in the contest, on an air-cooled Marmon car. L. H. Roberts, who succeeded, had the same make of machine with water-cooled engine. R. A. Greene piloted his own Locomobile, a 20-horsepower 1908 model, with yet very few miles to its credit, judging from the spotless condition of its paint and brass work. P. H. Johnston took the Grout touring car No. 11, and Mazzaro, Chilver, and Smith each steered a Mitchell.

The only "six" in the competition was a long-bonneted Ford runabout piloted by A. T. Purcell. F. P. Gillette was responsible for the safety of the 1908 Pullman, just shipped from the

COURSE WAS VARIED, INCLUDING LONG CLIMBS, AS WELL AS LEVEL STRETCHES.

York factory. In strong contrast with its competitors was Dr. J. Finley Bell's little Hewitt runabout, which was certainly not a 1908 model. Franklin supplied the second air-cooled car, with S. D. Atkinson at the wheel; Cadillac was represented by a single and a four-cylinder model, the latter a 1908 production with runabout body, handled by I. M. Uppercue. C. E. Fisher responded with a new Autocar, and Montague Roberts, equipped with a football helmet which

many a competitor would have gladly borrowed during the night, closed the procession on a 1908 Thomas Flyer touring car.

There was a generous and hearty response to the committee's request for cars to aid in the work of organization, the Calvert-Zusi Auto Company lending a 1908 Six-Teen-Six Winton touring car, with which C. S. Calvert carried pressmen around the course at a rapid clip until morning hours. Chester Henry's Pope-Hartford, after being used to lay out the course, was placed at the disposition of the quill-driving group. Official cars were L. T. Wiss' Packard, H. A. Bonnell's Jackson, C. C. Clawson's Buick, and F. A. Crosselmire's Oldsmobile. B. M. Shanley, who had assumed the duties of referee, had his own powerful Mercedes runabout to carry him to any point of the course.

### What Was Required of the Twenty-two Competitors.

Conditions of the competition were that each machine should cover five rounds of a 94-mile circuit during the twenty-four hours, without adjustments of any kind and without stopping the engine except when authorized to do so in control. There were no classes, the little single cylinder cars being asked to do all that was demanded of the powerful "sixes." Observers had been placed round the course, but no time was taken; even at the clubhouse control, where hour of arrival was noted, the contestants were not called upon to adhere to any running schedule, the only speed condition being that they should finish the run with not

SPECTATORS WERE NEVER LACKING AROUND THE NEW JERSEY CLUB HOUSE ON BROAD STREET DURING THE CONTEST.

"MONTY" ROBERTS AND HIS THOMAS NEVER FALTERED.

RALPH OWEN, A CLEAN SCORER WITH HIS OLDSMOBILE.

RYALL AND MATHESON, FIRST TO START, FIRST TO FINISH.

more than three minutes leeway on their starting time. An observer on each car, in most cases supplied from the Stevens Institute, saw to it that the conditions of the competition were adhered to on the road.

Excepting a broad stretch of road near Mount Freedom, where the width was so slight that passing was difficult, and the mud made speed impossible, the course was an excellent one. There were trolley and steam railroad crossings that needed to be approached carefully, three or four dangerous turns, notably the one near Dover, and several towns that needed to be traversed cautiously. Adequate provision had been made to insure safety, however, red flags noting the danger spots and arrows marking all the confusing turns. When the "darky" revellers around Succasunna hatched a plot to transpose all the road signs, the cars had all been round once, the drivers knew the road, and no one was deceived.

Favored with perfect autumnal weather and fair road conditions, the initial round through Bloomfield, Montclair, Verona, Parsippany, Dover, Kenvil, Mount Freedom, Morristown, Bedminster, Somerville, Scotch Plains, Springfield, Hilton, and Irvington to the clubhouse at Newark, was accomplished with few incidents. Nichols' Maxwell, owing to inattention to lubrication, burned out its connecting rod bearings and had to retire, together with its companion driven by McCormick, suffering from carburetor troubles. On one of the first stiff grades J. P. Hopson's Oldsmobile "Mudlark" was in difficulties owing to a slipping clutch, and only reached the top of the hill after vigorous efforts on the part of her passengers. The defect was remedied later and no further difficulty experienced, though it was impossible to obliterate the black points for adjustment.

#### One Accident Marred an Otherwise Perfect Day.

P. J. Gillette experienced some trouble with the gear shifter of his Pullman during the first round, but put matters right while the engine was running. On reaching Newark he stopped outside the clubhouse to check in and fill the gasoline tank. The operation was almost completed when suddenly the car burst into flames; in less time than it takes to realize it the gasoline tank had exploded and Peter La Greca, the mechanic, and Charles Parsons, the official observer, were enveloped in flames. There was a wild stampede for safety, and a rush to get Robert Ward's big Dietrich and the Pure Oil Company's 2,000-gallon gasoline tank wagon out of the danger zone. La Greca was carried to the clubrooms and treated by a doctor, the report being given out that although rather seriously injured he was in no danger. Reports as to the origin of the fire are as numerous as they are diversified; it is certain, however, that the control at the corner of Broad street and Clinton avenue was not sufficiently guarded with such a large quantity of inflammable liquid at hand. A couple of fire engines which arrived on the spot with due promptitude had nothing more to do than extinguish the smouldering embers of the bodywork of

the Pullman, the loss of which was estimated at \$2,000. After the accident precautionary measures were much more stringently observed, the gasoline supply wagon being isolated some yards down the road and each car roped off and all lights extinguished before filling of tanks was commenced.

Fast going had been the rule during the first round, some of the cars covering the ninety-four miles in a little less than three hours, and more than half of them coming round to the clubhouse in less than four hours. On the second round the little warmth of the afternoon sun had been withdrawn, with the result that passengers and drivers began to experience some of the disadvantages of fast traveling through a frost-bound country. The night was perfectly clear with a deep blue sky and bright moon, but the cold northeast wind destroyed all appreciation of nature's charms, the only thought of drivers and passengers being to keep out the freezing blast. Observers and passengers had smaller reason for complaint, for they could change at each round, and seek warmth and rest in the straw mattresses provided for them in the upper rooms of the club premises. The drivers, however, stuck to their task, the only change in their attitude as the night wore on being that exposed portions of their face grew smaller and smaller until at last only an ungainly mass of rugs and two eyes could be seen at the steering wheel.

#### A Few Rustics Greeted the Cars with Logs and Stones.

Compared with two years ago, the attitude of the rural populations towards the automobilists was pleasing, even enthusiastic in the towns. There were a few exceptions around Mount Freedom, where a stone hurled at the Matheson car smashed George Robertson's goggles and a passenger in another automobile was hit in the chest. Near Denville, too, logs were placed across the road at intervals of about two hundred feet. Hopson, on the Oldsmobile, discovered the obstruction soon enough to avoid an accident, and sent a telephone message to headquarters, on receipt of which the Winton press car was sent out to arouse the police authorities to their duty.

Dr. J. Finley Bell's small Hewitt runabout did not survive the second round, owing to losing time through exhaustion of its gasoline supply when far removed from the only station. E. A. Chilver's Mitchell broke the pump on the third round, overheating ensued and abandonment was decided upon. About 2:30 in the morning I. M. Uppercue, driving the four-cylinder Cadillac, ran into the bank near Somerville and smashed the front right wheel. Up to this time the car had been traveling very fast and was far ahead of the average of 19-miles an hour necessary to finish on schedule time. Ryall, who was the first to pass on his Matheson, brought the Cadillac driver into Newark and dropped him off at the local agency, the observer meanwhile staying near the car on the hillside. A new wheel was shipped out on another car, fitted to the disabled Cadillac and the journey resumed after a loss of about four hours. So fast had been the going, however, that all

FRANKLIN, THE ONLY AIR-COOLED CLEAN SCORER.

CLEAN SCORE LOCOMOBILE, DRIVEN CONTINUOUSLY BY R. A. GREENE, WAS A FAVORITE WITH THE LADIES.

MRS. RICKEY, WHO CONTINUED PLUCKILY TO THE END.

lost time was regained, and the Cadillac finally checked in on time, but with a heavy penalization score against it for replacements.

The second Marmon, the water-cooled variety, fell by the wayside during the night while trying to get round a hay wagon in charge of a sleepy driver. Roberts, who was steering the Marmon, followed the slow horse team along the narrow single-track road near Mount Freedom for a long distance, vainly endeavoring to clear a passage by repeated hoots of his horn. At last, thinking the road was sufficiently wide to allow of a passage, he speeded up his car for a rush, only to drop into a deep ditch and stick there hard and fast.

#### The Fleety Ones Had to Kill Time on Last Round.

By 9 A.M. fifteen cars had started out for the fifth and last round, seven of them having perfect scores and eight more or less penalization points. As the first competitor was not due to check in before 2 o'clock, no one had less than five hours for the ninety-four miles. Ryall, who had led all the way on his Matheson, quit the clubhouse at 8:30, having thus five and one-half hours to cover a circuit that he had once traveled in a little over three hours. According to regulations the cars must not stop for any reason during the last round, and should not travel in a circle, consequently the last round was as slow as some of the others had been fast. Charles Fleming's Maxwell, after leaving the clubhouse, went out of the competition, owing to difficulties with a leaky radiator, its abandonment leaving fourteen cars to finish.

Promptly at 2 o'clock No. 1 Matheson broke its way through the crowd of spectators gathered around the decorated clubhouse on Broad street and crossed the finishing line as a shout of welcome went up. Ryall limped down from his seat with the remark that he was not very tired and that he did not know where the tools were on his car. No work had been done on the engine during the twenty-four hours and the only care the Diamond tires had received was a little extra air on the commencement of the last round. Very little tire trouble was experienced on the

run, though to judge by the stocks carried on some of the cars, immunity from trouble was not expected. Probably, however, it mattered little to the drivers what impression was created in the mind of the layman by the sight of four or five spares.

R. G. Kelsey's racy-looking Haynes snorted over the line a minute after the Matheson, also with a perfect score. Ralph Owen's Oldsmobile, comfortably equipped with top and windshield, was another perfect scorer, followed by the Oldsmobile "Mud-lark," with 12 points penalization for adjustments to the clutch. R. A. Greene's Locomobile, with three lady passengers on the rear seat, arrived perfect, looking none the worse for its 470-mile trip; Mrs. Rickey's Marmon came scurrying round the bend at a rapid rate, several minutes behind its regulation time, and, as events proved, with 341 points against it. S. H. Rossman had taken the wheel during the night to relieve the lady driver, who continued, however, to travel round on the car, and was on the spot smiling when the test ended. Most of the penalization was caused through a leaky petcock causing loss of gasoline.

NINETY-FOUR-MILE COURSE ON WHICH CONTEST WAS HELD.

Although P. H. Johnston's Grout and Wm. Mazzocco's Mitchell both arrived on time, they were each penalized for stopping the engine and making adjustments on the road. The big Ford six-cylinder runabout went over the line with a perfect score, its rumble seat passenger and its observer being so enveloped in woolens as to be totally unrecognizable. S. D. Atkinson brought the air-cooled Franklin to the end of its journey with a perfect record. The single-cylinder Cadillac, the only one-lunger to complete the journey, was not favored by fortune. During the night, the engine was accidentally stalled as the result of running into a tree, and a penalization of 23 points incurred. For some time the committee considered the advisability of remitting the penalization in view of the exceptional circumstances, but finally decided to apply the rules rigorously, with the result that the Cadillac was removed from the perfect score list, although finishing on time and without adjustments. I. M. Uppercue's Cadillac, a four-cylinder runabout, went down with a marred record officially, but with an excellent performance to its credit. C. E. Fisher's four-seated Autocar runabout was another prompt arrival with a marred score due to adjustments on the road. Finally Montague Roberts pulled up on the spot he had started from, held out his watch for the inspection of the official, and furnished the seventh perfect scorer in the New Jersey twenty-four-hour endurance test. All seven drivers had remained at the wheel of their cars the entire twenty-four hours, and of the others only one or two allowed

WINTON SIX-TEEN-SIX, WHICH DELIGHTED THE PRESSMEN.

NEWARK'S MAYOR AND THE CLUB'S ENERGETIC COMMITTEE.

themselves to be relieved. The cars were put to a fairly severe touring test, but the physical strain was certainly greater than the mechanical one. It speaks much for the pluckiness of the drivers that they should have remained at their task so unflinchingly, though suffering severely from the cold during the night, and having none of the stimulants which are supplied by a track.

Half an hour after the last arrival the race committee had worked out the whole of the scores and communicated them to the press. Although under physical disability, Secretary Bonnell remained on duty throughout the whole twenty-four hours, and was well supported by a staff of officials who succeeded in making the event the most successful ever held in the State.

The score of the run:

MAKING GOOD TIME ON THE OLD NATIONAL PIKE.

One of the familiar covered bridges on the National Road near Harmony, Pa., a district in which they are a common sight. For quite a few miles the old national highway has an excellent surface in the part of Pennsylvania in question, and the stretch constitute as good link in a route for a fall tour.

## RECORDS IN RHODE ISLAND CLIMB.

PROVIDENCE, R. I., Nov. 16.—The fourth annual contest for the C. Prescott Knight Cup, under the auspices of the Rhode Island Automobile Club, which was also the sixth annual hill-climb of the latter organization, proved of considerable interest, as it afforded an excellent opportunity to compare the hill-climbing powers of the cars of to-day with those of three years ago, for it was in 1904 that the previous event was held on the grade at Riverpoint. The climb is a half-mile stretch, having an average grade of 14 per cent. and being as stiff as 23 per cent. in parts, while it is also made worse by hard turns. Cedrino in J. K. Crafford's "Fiat Cyclone" brought the 1904 record of :47 4-5 seconds down to :30 flat, and every other participant in the climb did far better than the old record. The next best time was that of L. F. N. Baldwin in a Stanley steamer, the latter bursting a steam pipe on the way up.

Interest naturally centered in the final free-for-all event for the Knight Cup. Dower in the Corbin led off, but the car skidded bodily into a stone wall at the foot of the hill; skillful handling that drew a cheer from the crowd kept the car going, however, and despite the accident the excellent time of :38 flat being made. Blackinton, in a 20-horsepower Stanley, was next, but could not do better than :34. Baldwin followed in the 30-horsepower Stanley, the steam connecting pipe of which burst about 100 feet from the finish, the car starting to roll down the hill backward. Baldwin applied to the judges to enter another car, but the request was refused.

In the other events Herbert A. Capron's 30-horsepower Pope-Hartford, driven by Grady, proved a most consistent performer. It took first in two classes, making the climb in :37 3-5 twice, and with a stripped Pope-Hartford the same driver clipped 3-5 off this in the free-for-all.

Other winners were D. W. Flint in his 15-horsepower Ford, time 49 seconds; J. H. Davis, driving J. A. Foster's 35-horsepower Oldsmobile, time 49 1-5 seconds; and John L. Snow in a 45-horsepower Peerless, which made the climb in :38 flat. In addition to the Knight Cup, which was offered for the fastest time regardless of class, a handsome silver trophy was awarded in each of the events. The climb was excellently managed, the running of the entire program being executed without the slightest hitch.

The officials in charge of the event were: Dr. Julian A. Chase, referee; William Penn Mather, R. Lincoln Lippitt, Darwin Almy and C. Prescott Knight, judges; John R. Dennis, Charles F. Almy and F. H. Smith, timers; Everett F. Boyden, starter, and Eugene M. Sawin, clerk of the course. The summary:

<b>GASOLINE CARS COSTING \$1,000 AND UNDER.</b>	
1. Ford, 15-h.p.; driver, D. W. Flint.....	:49
2. Ford, 15-h.p.; driver, A. B. Rust.....	:56 1-5

SCENE AT THE START OF THE EVREUX SPEED TEST ON A PERFECT STRETCH OF ROAD GUARDED BY 300 ARTILLERYMEN.

## EVREUX HILL-CLIMB HAD STARTERS IN PAIRS

PARIS, Nov. 11.—Racing events for 1908 have finally closed down with a meet at Evreux, sixty miles from Paris, participated in by over one hundred cars. Rigal, on the four-cylinder Darracq racer built for the Grand Prix, took first honors by covering the flying kilometer in 27 3-5, equal to 80 miles an hour, and marking up 1.13-5 for the mile standing start. These two records secured for him the Coupe d'Evreux, the most important trophy offered for competition. Though the road surface was perfect and the track securely guarded by troops, Rigal could not get full speed out of his racer for the kilometer run for fear of not being able to slow down sufficiently before striking a patch of greasy cobblestones.

The day's program had been arranged by the editor of *Les Sports* so that all competitors took the flying kilometer in the morning, and that the two first in each series should run together in the afternoon over the mile course, with a standing start. In every respect the innovation was a success, in several cases the cars being so evenly matched that they ran neck and

neck until within a few yards of the finishing post. Naturally such a method of racing was only possible on an exceptionally wide road with a perfect surface for the full width and well guarded by troops.

Hemery, on the Benz racer which he handled in the German Emperor's race, won in his own class, defeating a Minerva after a very keen struggle. In the Targa Florio class competition was equally intense between Metargy's Darracq and a Bayard-Clement, won by the former by a couple of lengths.

Although fast time was always made in the tourist class, public interest in the fourteen divisions might have been considerably lessened but for the system of sending the competitors away in pairs. Fastest time of any four-cylinder touring car was made by a Minerva, fully equipped for touring and driven by its owner. A Benz was second in the general classification and a Brasier third. Brasier took the first prize in the flexibility test with a six-cylinder car by covering the kilometer in 0.33 and 3.50. There were four other competitors. Paul Meyan's big Dietrich limousine with inclosed driver's seat—one of the largest closed bodies ever built—excited interest by covering the kilometer at the rate of 55 miles an hour.

## GERMANY'S PRINCIPAL 1908 EVENT.

BERLIN, Nov. 12.—The meeting of delegates of the clubs connected with the cartell of German automobile associates was held here with the Duke of Ratibor in the chair. The main features of the proceedings, which were attended by twenty clubs, was the question of the Prince Henry Tour, which is to be Germany's principal event next season and will take place in June, 1908. The basis for the regulations will be taken from those of the Herkomer tour, but official sanction must first be given before this matter can be entered into, as the clubs are rightly nervous of spending too much labor on what may be eventually vetoed. Letters were read from the Home office and Office of Public Works, stating that permission would in future only be granted to such tours as were absolutely indispensable for the welfare of the industry, and the South German and Rhenian clubs mentioned their intention of dropping the big tours and trials planned for next season. Uniform danger boards are to be put up throughout the empire, and an effort will be made to induce the Prussian Government to send a representative to the meeting of Government delegates to regulate motor traffic on the Continent.

FRENCH STATESMEN HAVING EXPERIENCE WITH TIRE INFLATION.

Premier Clemenceau and Deputy Jaurès, the socialist firebrand of the French Government, have been caught by the enterprising photographer in the act of inflating their automobile tires, the former with the aid of a compressed air tank, the latter by the more vigorous method of the hand pump. Unfortunately for the romance of the story veracity compels the admission that the political leaders were not present in the flesh, but in wax.

LOUIS BLÉRIOT'S AEROPLANE, WITH ANTOINETTE MOTOR, MAKING ITS FIRST APPEARANCE AT ISSY-LES-MOULINEAUX, NEAR PARIS.

## EIGHT FLYING MACHINES BUSY ROUND PARIS

PARIS, Nov. 12.—With the *Ville de Paris* and the *Patrie* in the air and the heavier-than-air flying machines of Farman, Comte de la Vaulx, Delagrangé, Blériot, Santos-Dumont, and Pelterie skimming over or on the ground every day, there is no lack of interest in aeronautics around Paris.

Louis Blériot, since discarding last year's moderately successful cellular aeroplane, has been busy on a new model, which was tried out for the first time this week on the Issy-les-Moulineaux drill ground in foggy weather. The new machine is of the monoplane type, eleven yards in width from tip to tip, and thirty square yards bearing surface. To the rear of the two main wings is the elevating rudder divided into two independent sections, and surmounted by a vertical rudder. The engine, a 50-horsepower Antoinette, of the same type as that used by Farman, is carried forward, where it is coupled direct to a four-bladed propeller. A peculiarity of the construction is that the framework of the machine is covered with a special varnished paper, giving considerable strength with minimum weight. The aeroplane is mounted on three rubber-tired wheels, two forward and one in the rear, the latter one being fixed to the vertical rudder and turning with it.

On the trial trip the steering gear was somewhat stiff, the pilot only being able to get the steering wheel out of a straight line after considerable exertion, and then in an abrupt manner. After a few runs under these conditions, the motor pulling well and the machine acting in a fairly satisfactory manner, the rear wheel was bent under the strain and the tests abandoned.

Later in the day Comte de la Vaulx made the first public appearance with his new heavier-than-air machine on the Saint-Cyr military ground. The machine, which is also of the monoplane type, and is driven by an eight-cylinder 50-horsepower Antoinette engine, has a couple of propellers to the rear of the bearing surface, and turning in opposite directions. For the first trip Comte de la Vaulx satisfied himself with runs across the ground to familiarize himself with the working of the machine. Despite the heavy, clay surface, the speed was satisfactory, it being necessary to cut out the ignition to prevent flight.

Henry Farman, who has admittedly got a long lead on all his aeronautical rivals, has been quietly training at Issy every day during the past week and has made several flights varying from 300 yards to almost 800 yards in a straight line. On two occasions he has come back to his starting point and descended to earth without injury to the aeroplane. On the last occasion, however, in the presence of a crowd of 2,000 persons, who

somewhat hindered the movements of the flyer, Farman came down too abruptly and broke one of the wheels. Instead of repairing, he has decided to commence the construction of another aeroplane of smaller area, to be driven by a Panhard-Levassor motor of 100 horsepower. His abstention leaves the \$20,000 Deutsch-Archdeacon prize in abeyance for a time, for although Santos-Dumont has brought out *No. 19* and has invoked the Contest Committee to witness a performance, he is not yet sufficiently in training to accomplish a circular flight.

Lieutenant Lahm, winner of the first international aeronautical cup race, has made an ascension with Hon. C. S. Rolls, from Short's balloon works at Chelsea, London, to Chelmsford. The feature of the trip was that it was intended to descend as near as possible to the house of Claud Crompton, an enthusiastic Chelmsford aeronaut. Wind being favorable, this was done with ease.

### Balloon Trips to Order in New England.

BOSTON, Nov. 18.—Arrangements have been made by the Pittsfield Aero Club to make ballooning one of the most popular sports in 1908. According to Charles J. Glidden, a balloon garage will be built and arrangements will be made with the gas company for six ascensions daily. To make a trip all that will be necessary will be to telephone or telegraph the club and in two hours a balloon will be inflated and ready for a journey.

BLÉRIOT SEATED ON HIS BIRD-LIKE FLYER.

## SAVANNAH MAY SUPPLY ROAD COURSE, SOLDIER GUARDED

SAVANNAH, GA., Nov. 18.—The Savannah Automobile Club is powerfully interested in a proposed stock chassis race, to be held in January next. For some time past members of the club have been quietly making progress in this direction, and a number of the most influential citizens, including Mayor George W. Tiedeman, have given the proposition their hearty sanction. There is a ten-mile stretch of the finest road possible in the outskirts of the city, and it is possible to add as many miles more should it become necessary. The course is easily reached from the city, and application has been made to the County Commissioners for the use of the road for the proposed race, and it is understood that such permission will be readily granted. The road and all interesting highways would be closed to traffic, and application will be made to the proper authorities for the use of the Georgia State militia, stationed in Savannah, to help police the course. It is expected that there would not be any difficulty in obtaining the assistance of the local State militia.

The plans for the race were thoroughly discussed at a meeting in the Hotel de Sota last week, and one of those in attendance was C. Wood Tatham, of New York City, who is more or

less responsible in bringing the proposition to the attention of the local automobile club.

No difficulty will be experienced in financing the scheme, and sufficient money will be subscribed by those interested in the contest to put the roads in the best possible condition, supplying telephonic communication at different points on the route and supplying visiting autoists and contestants with sufficient garage accommodations. Two or three New York autoists have looked over the proposed course and state that it will afford every facility demanded of a stock car race.

Another meeting will be held within the next few days, and invitations will then be extended to the leading manufacturers and other prominent motorists to visit the course, if possible, and offer any suggestions. The Savannah authorities will also ask the American Automobile Association to sanction the event when the details are thoroughly worked out. The long-distance stock car race, however, will not be the only automobile event to be held, as it is proposed to conduct a series of interesting events during the winter, the entries, of course, determining the exact nature of the other races.

## AN AUTOWAY TO THE TOMB OF WASHINGTON

WASHINGTON, D. C., Nov. 18.—Every automobilist in Washington has constituted himself a committee of one to help along the work of the Mount Vernon Association in constructing a boulevard from Alexandria to the home of George Washington at Mount Vernon, Va. Preliminary steps have already been taken. The circuit courts of the counties of Alexandria and Fairfax, Va., will soon be requested to appoint commissioners to ascertain what property it would be necessary to condemn for such a highway, and to estimate the resulting damages and benefits. As soon as the cost can be accurately estimated it is proposed to begin an active campaign for the construction of the boulevard.

This project is one that deserves the cordial support of the public. The existing road leading to Mount Vernon should

be superseded by a modern, broad driveway, in order to render as accessible as possible the spot regarded as sacred by all Americans. At the present time it is impracticable to reach Mount Vernon by automobile on account of the exceedingly bad road. The highway connecting Mount Vernon with Washington is a rare antique—one of the relics of the old heart-breaking days when life was largely spent in struggle with adverse nature. That this road should remain to this day is an anomaly.

With a broad, properly prepared roadway, the journey to the home of Washington would become a pleasantly memorable experience to hundreds of Washington automobilists, to say nothing of the hundreds of automobilists who come to the National Capital every year in their cars.

## GERMANY'S DENATURED ALCOHOL EFFORTS

CONSUL T. J. Albert, of Brunswick, Germany, writes that at a recent agricultural congress the question was considered as to what measures seemed appropriate for the general extension of the use of spirits for technical purposes, as follows:

It was stated that the first and most important point for the possibility of an extended technical application of spirits was the establishment of the price. This is influenced by two factors, first, the cost of production, and second, by legislative revenue measures which operate to make spirits dearer or cheaper.

As the cost of production of spirits cannot be lowered under certain limits without destroying the value and importance of its production to agriculture, and as the lowering of the price is an essential condition for its introduction into use for technical purposes, attention must be directed to the point that spirits after leaving the distillery or place of manufacture experience no increase in price which can be possibly avoided. In order to accomplish this, spirits destined to be used for technical purposes should be free from any fiscal tax or, as is the case in Germany, a premium in the shape of a rebat should be paid at the expense of spirits used for drinking purposes.

The cost of denaturing spirits should also be reduced as low as possible by the choice of suitable materials for denaturing, and this cost not increased by fees levied for denaturation. The process used in Germany, which allows spirits which are to be used for motive power to be denatured by the far cheaper material, ben-

zol, in place of one-half of the materials ordinarily necessary for the purpose, was commended. In any case the choice of the cheapest possible material for denaturing should not lead to the employment of materials which would have an unfavorable influence on the spirits in its various ways of application, or materials which by simple manipulation can be removed or remain concealed in the spirits.

In order to prevent the arbitrary advance in the price of spirits by the retail trade, to which it is not seldom subjected, it was suggested that the central distributing stations which supply the retail trade with their goods should make known by continuous advertising throughout the territory concerned the proper retail prices of spirits, and, further, that the co-operation of the retail trade in cheapening prices should be compelled by official restraints, such as granting of licenses of sale upon conditions or by official control.

In Germany the tax on domestic spirits per liter (1.0567 quarts) of pure alcohol is 22 1-2 cents, of which 17 cents is for consumption excise, 4 cents for mash-tub tax, and 1 1-2 cents for distilling tax. Upon application to the proper authority this tax is refunded on spirits used for drinking purposes when exported, and also on alcohol used in perfumeries, head, tooth, and mouth washes, and fluid alcoholic medicines, and for certain ethers.

The present distillery price of refined spirits for 100 liters pure alcohol taxed is \$30, while the price for denatured spirits 90 per cent. alcohol is \$5.95 per 100 liters.

# CONCERNING THE PROGRESS OF IGNITION

By CHARLES B. HAYWARD.

WHEN the problem of successfully maintaining a current of one or two amperes at six to eight volts on an automobile was presented to electrical experts by the sorely puzzled manufacturers of several years ago, they looked upon it as something in the light of child's play, and, as such, immensely beneath their dignity to be concerned with. To men who were studying the problems of generating thousands of horsepower at increasingly high voltages, and of transmitting it efficiently over long distances, the idea of not being able to successfully achieve such a ridiculously trivial thing as this appeared absurd. As a result, the ignition problem, which was long one of the most pressing that the automobile builder had to contend with, was left entirely to him and his confrères in the accessory manufacturing line to solve. Few, if any, of the high-priced experts employed by the large companies regarded the matter with anything but complacent and indulgent skepticism of the "I-could-show-you-how-to-do-it-in-short-order" type, and those same companies which were turning out millions of dollars' worth of electrical apparatus apparently never looked upon the automobile ignition field as anything to which their unequalled facilities could be profitably devoted. It is worthy of note in this connection that one company, which literally turns out millions of magnetos and induction coils for telephone purposes, has just taken up the manufacture of ignition spark coils, while another and one of the largest manufacturers of electrical apparatus in the world is now turning its attention to the production of a magneto.

So it came about that the development of the ignition system of the automobile was left largely to the resources of the automobile designer, who knew the conditions but had little conception of the electrical requirements, and the accessory maker, who at that time had no knowledge of the former and was far from being well posted where the latter was concerned. Electric ignition was nothing new, but the fact that a battery, an induction coil, a timer and a plug did not necessarily constitute an efficient ignition system was no better realized six years ago than the fact that a gasoline engine and a running gear did not make an automobile.

## Early Coils Were Extremely Crude.

As practice in this country has tended more to the adoption of the high-tension type of ignition, most of the progress in this field centers about the latter where the American maker is concerned.

And when the crudity of the apparatus that the pioneer makers had to contend with is borne in mind it is small wonder that the ignition system was long the *bête noir* of the autoist. As a matter of fact, in spite of its extended use in the telephone, the induc-

tion coil had progressed but little from the days of Rhumkorff—its efficiency was about on a par with the wooden axle of our forefathers as compared with the modern ball-bearing. With the exception of such large coils as were specially made for laboratory use, the manufacture of induction coils was entirely according to rule of thumb, and it is to the simultaneous development of wireless telegraphy and the automobile, but more to the latter, that the scientific investigation devoted to the subject in the interim is due.

A great amount of study and experiment had been carried on with a view to raising the efficiency of large transformers for commercial use, but, as already mentioned, the sparking coil was then considered too petty an affair to merit serious attention, except on the part of those directly engaged in its manufacture for automobile use. It is stated on good authority that the efficiency of the majority of the earlier coils seldom exceeded 15 per cent., a fact that readily accounts for the disheartening rapidity with which a set of dry cells became exhausted. But there was no data on which to base standards—cores were made either much too large or too small, usually the former, making a mass of iron that could not be quickly magnetized and demagnetized; the wire of the secondary winding was frequently too fine and there was too much of it, making the resistance of the secondary coil too high; condensers were poorly balanced and vibrator speeds were very low owing to the crude design of this essential—in short, it had always been considered that coarse wire wound about an iron core and a fine winding over that made an induction coil. Some of those old-time coils had a seven or eight-inch core with number 40, or even finer wire in the secondary, and as a consequence of the latter their resistance was as high as 7,000 to 8,000 ohms.

In contrast with this, the resistance of the modern coil ranges from 2,500 to 5,000 ohms, it has a core measuring on the average 1-2 by 5 inches, and the secondary winding is of number 36 wire, while the vibrator speeds are now as high as 80,000 per minute, as compared with 15,000 to 20,000 of the old coils. These appear to be simple changes in design, but it required endless study and experiment to bring them about. It was known that special grades of iron were required for the cores, but further than this no study of the qualifications necessary in this essential had been undertaken up to within a comparatively short time ago.

In the past five years the efficiency of the induction coil designed for automobile use has been practically trebled, for which scientific study of the requirements has been almost wholly responsible. It was realized that the hysteresis qualities of the core were an extremely important factor in limiting vi-

FIG. 2.—Method of fastening and drive of the Bosch high-tension magneto on the Lozier.

FIG. 4.—Method of advancing and retarding the timing of the spark on Eisemann magneto as mounted on the Peerless.

FIG. 5.—Drive of special low-tension magneto taken from short independent shaft forward on the Locomobile.

an instrument for testing this quality of iron. It consists of a special form of generator with a bi-polar field, between the pole pieces of which the sample to be tested is revolved. The winding of the field is independently energized by one milliamper of current, this factor thus being a constant, the resistance of this field and that of the second armature carrying the indicating pointer being the same. According to the character of the path for the magnetic flux presented by the revolving sample of iron, the pointer is deflected more or less, and it is said to be nothing unusual to find that samples of iron differ 20 to 30 degrees, the scale of the instrument being calibrated according to a standard evolved by the inventor.

Mr. Heinze has also devised an extremely ingenious instrument to measure the relative temperatures of the secondary sparks produced by different coils, this being patterned after the principle of the hot-wire pyrometer, and forming an extremely sensitive indicator of varying degrees of temperature as is essential with the slight amount of heat produced by the spark. Both these and a standard form of milliamperemeter for the measurement of secondary currents have played an important part in the development of the Heinze coils, while similar painstaking investigations have been carried on by the makers of other well known spark coils in their laboratories, of which the makers of the Splitdorf, Connecticut, and Pittsfield coils may be cited as instances.

#### Improvement of Sources of Current Supply.

In view of the capacity of the old-time coil for wasting current, which was also a characteristic of many timers, it is scarcely to be marveled at that the dry cells of those days did not acquit themselves over creditably. There was much to be learned about the making of dry cells for automobile use and this was even more true of the storage cell, as the latter had never been employed under similar conditions previously. Just what changes the makers of dry cells have made in their product to bring about the result is usually a trade secret in each case, but the fact remains that the average output of the modern dry cell, such as

FIG. 6.—Placing of the Remy high-tension magneto on the Apperson; the independent driving is actually much longer proportionately than it appears in the foregoing sketch.

brator speeds, as had been the excessive amount of iron first used, as the rate of vibrator working naturally depends upon the rapidity with which the core is capable of becoming magnetized and demagnetized. As a means of determining this, John Heinze, of the Heinze Electric Company, Lowell, Mass., has devised

the Columbia or Ever-Ready brands, is now well in excess of 20 amperes when new, where formerly it seldom exceeded 15. While the efficiency of the storage cell designed for automobile use has been correspondingly increased, it has been largely a matter of adaptation to new conditions, and this has been carried out so thoroughly in some of the better known makes such as the Witherbee, National, Geiszler, Royal, Vivax, Rex, Porox and others that there is little left to be desired, though, as will be obvious from the foregoing, the sins of the coil and other parts of the ignition system are easy to attribute to the battery.

Improved forms of grids, special methods of pasting, new forms of insulators, improved gas vents, and special compositions for the active material, as well as a study of the requirements of the strenuous service required for an automobile ignition battery, have all contributed to bring the small accumulator to a state of perfection where troubles from shortcircuiting

FIG. 7.—Gianoli high-tension magneto with independently operated distributor forming service ignition system of the Columbia gasoline-electric.

through disintegrated plates, buckling and sulphating are comparatively unknown, for which, of course, the increased knowledge on the part of the autoist in handling the battery is in a measure also responsible.

It goes without saying that the most important step in advance, where the source of current supply is considered, has been the development of the magneto, and it appears only logical that with the immense amount of surplus power of the average automobile motor that a small fraction of it should be utilized for generating the ignition current—in other words, that the source of ignition current should be mechanical and thus better within the control of the driver, rather than chemical. Foreign

practice in this regard has always favored the magneto, while in earlier years the tendency was more toward the small direct-current generator. The latter has undergone great improvement, and though more or less generally used, as represented by the Apple apparatus, has not found favor to

FIG. 8.—Simple enclosed drive of the Bosch high-tension magneto on the new Selden 45-horse-power car.

the same extent as the magneto. Two systems of the latter have been developed for high-tension service, the Bosch of the true high-tension type and the Eisemann of the high-tension-with-coil type, of which the Remy, Pittsfield, Heinze, Dow and Holley are also examples, though the last-named embodies several special features, while the Splitdorf and the U & H belong to the former class, and the makers of the Remy are just introducing a machine of this kind of special design. The K-W magneto is an American machine using a coil, but is of the constant generating type and is characterized by numerous distinctive points of design, which place it in a class by itself.

Improvement in the mechanical generator has taken the form of refined construction rather than the adoption of new prin-

FIG. 9.—Special Holley high-tension magneto designed for small high-speed, four-cylinder motors such as the Ford.

the make-and-break system of ignition has not met with much favor at the hands of American makers, such cars as the Locomobile, Studebaker, Columbia and one or two others such as the Premier employing it. The first-named uses a special magneto made in the home factory, while the Bosch low-tension machine is usually favored on the others.

Though practice is rapidly approaching a standard in this respect, considerable diversity in the mounting and drive of this essential of the power plant is shown by various cars, as will be evident from the accompanying sketches. Some representative examples of this were to be seen in the Garden. Among the different makes noted are the Remy on the Apperson, the Bosch on the Lozier, Selden, Franklin six-cylinder, Stearns, Thomas, Pierce, Matheson and others, while the Eise-

FIG. 10.—Details of the positive self-starting device employed on the U & H magneto.

mann is to be found on the Packard, Peerless, Winton, Walter and Pope-Toledo, though an option of either of these makes is given on the latter car; on the Columbia gasoline-electric the Gianoli high-tension magneto is employed. In every one of the foregoing instances a dual system of ignition is fitted, and practice in this regard may be catalogued as an improvement, as, despite the advances made in ignition systems as a whole, their fallibility has thus come to be recognized in a-practical manner and suitably provided for. In numerous cases this takes the form of a completely independent duplicate system of the standard unit-coil and accumulator type, using a separate set of plugs, while in others the duplication is not carried this far, the distributor of the magneto and the same plugs being utilized in both cases. Taken all in all, the magneto has been perfected to a point where Continental practice in fitting it alone as a means of ignition should soon be followed here on cars the list price of which does not permit of installing two systems. Starting on the magneto

ciples, though better distributor design and primary circuit - breaker have also largely contributed toward the unusually high degree of simplicity and reliability that is now a feature of the magneto. As the low-tension magneto has always represented an electrical generator in its simplest form, nothing further in this direction was to be looked for, but despite this

has been made practically as easy as with a battery, though in this connection the special starting device incorporated in the U. & H. German magneto is of interest. It consists of an arrangement which permits of spinning the armature.

Early trials proved the single coil and distributor system to be productive of endless trouble on the secondary side, which caused its virtual abandonment at that time, but its manifest simplicity has brought about a renewal of interest in it, while improvements in high-tension distributors made in the meantime now permit of its use on the same plane of efficiency as the unit-coil type. The Mosler apparatus is an instance of this, while the Leavitt ball-bearing timer and distributor is an example of the improved form of device now employed for handling the high-tension current. Then there are special systems, such as the Atwater-Kent "spark generator," which is a self-contained unit adapted to be mounted on the dash of the car and driven from the camshaft of the motor. This is designed to be used in connection with batteries and consists of a single non-vibrating coil with appropriate mechanism for both the low and high-tension currents.

On the other hand, there is a decided tendency to retain the four unit coils and to make their working synchronous by eliminating the vibrators and controlling their action by the use of a fifth vibrator coil. As this "master vibrator" works the same for each cylinder, it insures regular firing, as well as much greater ease of adjustment and consequent economy in current. Instances of this are to be found in the Splitdorf system, a feature of which is the use of an individual switch on each non-vibrating coil to facilitate testing, and in the K-W system in which the K-W magneto is employed as the source of current. A system of this kind that marks a considerable departure is that brought out by the Western Electric Company, in which the four unit coils are assembled in an insulating case placed right on the motor. This case is permanently fixed in place and contains all the primary and secondary connections, so that the coils simply have to be slipped in. On the dash a twin vibrating coil is used, one of the units being provided as an emergency. For shifting from one to the other, a pole-changing switch is employed, thus preserving the contact points of the vibrator against the pitting action which ensues from continuously sending the current through it in one direction.

The weak points of every ignition system of earlier days were to be found in these essentials, and, next to the coils, they ranked high as sources of trouble. If the truth were to be told, the plug was suspected far too often and the timer far too little, and this is probably the case even at present. The timers that had been in use prior to the advent of the automobile gave satisfactory service at speeds of 300 r.p.m. or less,

FIG. 12.—Splitdorf synchronous, "master vibrator" system as mounted for demonstration to show its unusual efficiency.

FIG. 13.—How the Atwater-Kent "spark generator" was run more than the equivalent of 4,000 miles on six dry-cells.

FIG. 11.—Pittsfield high-tension with coil type of magneto, mounted for demonstrating purposes, the coil ordinarily being placed on the dash.

FIG. 14.—Illustrating the unusual location of the coils in the Western Electric "master-vibrator" system which is distinguished by the use of an emergency coil and a pole-changing switch.

for which they were designed, but rapidly went to pieces at higher speeds under the severe duty imposed on a car. The designer was confronted by the task of striking a medium between two essential but divergent qualities—the wipe contact type was superior electrically, while the ball contact type was by far the better form of construction. The former has been gradually eliminated, its place being taken almost altogether by ball or roller contact timers, the Bemus being a good example of the first named. Flimsy construction and poor materials were really at the foundation of all the early timer troubles and these have been practically done away with by the use of steel, bronze and better insulating materials, the employment of ball bearings and the possibility of filling the timer with a lubricant.

In a measure the same thing applies to the spark plug; porcelains were of poor quality and ill adapted to the service required and as a matter of fact, in common with many other things about the motor, these requirements were not any too well understood. Study of the principles involved and improvement in the materials employed, as well as in the workmanship, has been responsible for the vast advances made. The truth of this will be apparent on a little reflection, for while the ignition apparatus of the present day is about as far removed from that of a few years ago as it is possible to imagine, the principle remains the same. There have been no radical changes in this respect where any of the various essentials are concerned, nor, for that matter, in the manner of combining them that has prevailed from the first.

It has been almost entirely a matter of improving upon standards which were found in existence when the automobile came into being, and that this was not always brought about directly will be seen when it is recalled that the single-coil system of ignition was almost universally abandoned after but a comparatively short trial. Now it is being taken up again, both in its original and in a modified form, but it must be admitted that it was really the

FIG. 15.—The Mosler synchronized system designed to be placed in a glass case on dash.

FIG. 16.—Odd location and drive of the primary timer on the Corbin. This is brought out at right angles between the central cylinders.

shortcomings of the timer and the coil trembler that caused its early abandonment, and not any inherent defect in the system itself. It was found impossible to confine the secondary current within bounds with the facilities then offered by timers and distributors and the vibrating mechanism of the single coil employed was frequently faulty to a degree undreamed of by the present-day autoist, whose experience does not date back to a time that, somehow or other, no one ever thinks of as the "good old days." A hundred-mile trip in a day was then unusual, but a twenty-mile trip that did not give rise to more or less frequent necessity for vibrator adjustment or similar tampering with some other part of the ignition system, was far more so.

FIG. 17.—Part sectional plan and longitudinal section of the Leavitt distributor showing its simplicity.

Even the wiring of that day was only a makeshift, but it was the best that could be done, for there was no insulated wire on the market specially designed to carry high-tension currents under such adverse conditions as those which prevailed under the bonnet or, as often as not, under the body of one of those old-timers which represented a maximum degree of inaccessibility.

But to get back to the fact that, with all the improvement that has been accomplished, original principles have been adhered to throughout, it is safe to say that nothing furnishes a better illustration of this than the spark plug. Just who was responsible for the original of this essential does not appear at the moment, but ever since the time when Renault brought out the fact prominently that electric ignition on the automobile was a practical success by winning a long-distance road race with a car thus equipped, the spark plug has adhered closely to original principles, and in very many cases to original lines of construction. It will be recalled that in the early days European builders were extremely skeptical of the electric method of ignition, and the hot tube was very general, at least one continuing it even after having adopted electricity, though the American makers used the latter from the first.

Every spark plug consists essentially of an insulated terminal or electrode adapted to be screwed into the cylinder head, the body of the plug thus forming the ground or return connection, and much of the experimenting has been with a view to improving the qualities of the insulating material. Mica, lava, artificial stone and many special compounds have all been pressed into service, despite which porcelain has still continued to hold its own. Glass is the latest of these substances to be employed, as embodied in the Anderson plug. Other improvements have taken the shape of modified forms of terminals, such as the Reliance, in which the insulated electrode is ground off flush with the insulating porcelain; the placing of this terminal in recesses or chambered ends, as in the well-known Spitfire plug, the "Vim" plug, here shown, and a number of others, while accessibility has also been taken into consideration, as is evident from the development of the Breech-block plug, the Brown "Separable lock" plug and others.

FIG. 18.—Illustrating some recent developments in spark plugs. From left to right these are the K.-W. "Vim" plug, the "Reliance," the "Edco," the Anderson glass-insulator plug, and the "Breech-block" plug.

## THE PERFECT AUTOMOBILE: A LAYMAN'S IDEA

By G. H. GODLEY.

EVERY automobilist has his own idea of the perfect car, or at least of some parts of it. Many of these ideas are doubtless impracticable, but still there should be a large number of useful ones in the number. This "perfect car" does not lay claim to any deep research or experiment; it is merely a collection of such ideas reduced to paper. There is nothing startlingly original in it, either; the units of engine, gears, and frame are commonplace enough, but have never before, to my knowledge, been combined in just this way.

First to be considered are the general dimensions of the car. The present tendency seems to be toward wheel-bases of ten to eleven feet, thirty-six inch wheels, and motors of forty to sixty horsepower. I am convinced, however, that such cars are out of place on our roads. On rough going they are invariably out-paced by lighter and handier cars, and even under the best conditions, short of a race-track, they are not capable of any speed which a thirty-horsepower machine cannot equal. On hills the large car may have a shade the better of it; but most of our

In the details of the motor it is hard to come to definite conclusions, for the reason that motors as far apart in design as the two poles do their work with apparently the same efficiency and reliability. In this case the aim should be toward simplicity, as it is safe to say that the motor with the fewest parts will cost the least, both originally and for maintenance and will have the longest life. Of course, the simplest of all motors is the two-cycle, but this, in my estimation, has defects which put it entirely out of the question—chiefly its reliance on the incoming gases to clean out the exhaust, and its use of the crank-case for a pumping cylinder. Granted, then, a four-cylinder, four-cycle engine, I would first offset the cylinders from the crankshaft, securing a more direct downward thrust on the power stroke. Valves should be all on one side, thus dispensing with one camshaft and giving a more compact combustion chamber; and that one side should be the right, because with the centers of the cylinders to the left of the crankshaft this will make the motor more symmetrical, and the cams will be lubricated by

OUTLINE DESIGN OF THE PERFECT CAR, AS EMBODIED IN MR. GODLEY'S APPENDED DESCRIPTION.

hill roads are so crooked and broken with thank-you-ma'ams that it is unsafe to drive at more than a very moderate speed. For average service, then, fifty horsepower has no advantage over thirty. Also it is vastly more expensive in gasoline and tires, as well as in first cost, so that the buyer, for perhaps double the outlay, gets no more than his neighbor with a smaller car, except sheer bulk of steel and aluminum. Therefore my "perfect car" is of thirty horsepower, with a wheelbase of 112 inches and weight (though this of course is uncertain) of not more than 2,300 pounds.

A number of makers are loudly proclaiming that this, too, is to be a six-cylinder year; and doubtless there will be more six-cylinder cars built this year than ever before. But it should be remembered that there will be more four-cylinder cars built, too. I do not deny that the six-cylinder motor has numerous advantages, and I confess I seriously thought of putting one in the "perfect car"—until I began the design. Then I found that a six-cylinder motor 4x4 1-2 inches would take 38 3-4 inches under the hood, while a four cylinder 4 1-2x5 inches only took 30 3-4 inches. To install the six-cylinder motor my 112-inch wheelbase would have to be increased to 120 inches, with a consequent increase of weight and awkwardness. So the "perfect car" retains its four-cylinder motor, with a bore of 4 1-2 inches and stroke 5 inches—dimensions which, by the A. L. A. M. formula at least, should give thirty full horsepower.

the direct splash of the cranks. Cylinders are cast in pairs, as with the modern methods this is no more difficult than casting them separately, and will shorten the motor and simplify both the inlet and exhaust manifolds as well as the water piping.

The carbureter is, of course, automatic, and should have the float concentric with the spraying nozzle; and although I have never had the opportunity to try one, I favor the type with the Venturi tube air passage. Any device which does away with the extra air valve must be at least praiseworthy. The throttle-valve should be of the balanced piston type, and arranged so that when moved beyond the closed position it admits pure air into the cylinders. This is useful when coasting with the engine as brake, as it does not waste gasoline, and prevents the muffler explosions which usually follow when the spark is switched on again.

Ignition is by a magneto generating a low-tension current, with separate timer, spark-coil, and distributor; these are also used for the current from the storage battery, when starting on the spark. I know it is the ordinary practice to furnish two complete ignition outfits, even to the spark-plugs, but this seems unnecessary. It is also likely to make the operator careless, with the result that in a short time neither system is in working order.

A vertical-tube radiator with belt-driven fan, and centrifugal pump takes care of the cooling. The radiator, a modified "Mercedes" in outline, rests on the front cross-member of the

frame. The pump and fan-belt pulley are placed on the same shaft as the magneto, on the left side of the engine, and are driven from the crank-shaft through an idler. For lubrication the familiar one-pump system is used. This is about the simplest method ever devised except the old-fashioned plain splash, and always gives good results. Also it has no adjustments to be tampered with.

The clutch is the old reliable leather-faced cone, brought up-to-date by the addition of cork inserts. The cone proper is of aluminum, made as light as possible to reduce the inertia; and the cork inserts, together with correct proportioning, give a smooth, progressive engagement. This type is much lighter than the multiple-disk, has about five parts to the multiple-disk's fifty, and gives just as good results. From the clutch the power is transmitted from the change-gear on the rear axle by a shaft with two universal joints. As the motor is hung low on the frame, the joints work at a very small angle, and the friction loss in them is almost negligible. I have chosen the shaft drive in preference to the double-chain because it is quieter, more easily protected from dust and mud, and more efficient.

The change-gear is the standard three-speed and reverse selective type. It is placed on the rear axle for the sake of simplicity—one unit in the place of two. The modern change-gear is so light and compact that it hardly seems worth while to put in a sub-frame to carry it separately. The case is cast steel, integral with the central part of the axle housing; the stiffening ribs are on the inside, giving a smooth outer surface which will not collect mud. The change-gear shafts and gears are removable from the front end of the casing, the differential and bevel gears from the rear end. The live shaft is floating, with clutches to drive the hubs.

Both sets of brakes are on the hubs, but use separate drums, one inside the other, those for the contracting emergency brakes being 14 inches in diameter, and those for the expanding foot brakes being 12 inches. This arrangement helps to keep the brakes cool on long hills. The emergency brakes throw out the clutch when applied, but the foot brakes do not, thus enabling the driver to use the motor as a brake at the same time. The front axle is the usual I-section, drop-forged in one piece, with reversed Elliot steering knuckles. The steering gear is of the screw-and-nut type, with a 16-inch hand wheel on which the spark and throttle levers are mounted. Road wheels are 34 inches in diameter, shod with 3 1-2-inch quick-detachable tires in front and 4-inch in rear. Some drivers object to the use of different sized tires on front and rear wheels on the ground that this makes it impossible to exchange the front and rear tires after they are a little worn, in order to obtain more mileage. It does not seem to occur to them that this admission that their rear tires wear out faster than the front ones is the strongest reason why the rear tires should be made larger. As for the necessity of carrying two spare shoes instead of one when touring, personally I carry none at all. They are clumsy and always in the way, and nowadays, with a garage in every county seat, they are never absolutely necessary.

The frame, of course, is channel-section pressed steel, narrowed in front and raised slightly over the rear axle. Springs should be very wide, with a large number of thin leaves. There seems to be a general feeling that two ordinary semi-elliptic springs are not enough for the rear end of the car. Some makers have tried increasing their length, even to as much as 56 inches; others use three-quarter or full elliptics, but I think the best type is the platform. Some good make of shock absorber should be furnished as part of the regular equipment.

In all parts of the chassis vanadium steel should be used wherever desirable. I do not pretend to any very great learning on the subject of alloy steels, but everybody knows that continued vibration will break ordinary steel, no matter how strong in section. Hess-Bright or some equally good type of radial ball-bearing should be used everywhere except in the motor. Several makers put these on crank shafts as well, and they undoubtedly stand up there, but owing to the large sizes necessary they are

too expensive to be considered for a medium-priced car.

The length of the chassis allows 78 3-4 inches from the dash to the center of the rear axle, which is ample for a side entrance body. The car seats five and the tonneau seat is well forward over the axle, which with the platform springs should make it very comfortable. Few cars have any room for baggage, even of the most necessary sort. On a certain medium-priced machine the "baggage compartment" is a hole under the rear seat about two and a half feet long by one foot wide, but as the opening into it is two inches smaller each way it is impossible even to make the best of what little space there is. On the "perfect car" there is room for a trunk 33 inches long, 21 inches wide and 12 inches deep, partly under the rear seat and projecting back flush with the rear cross member. The floor boards both front and rear are of cast aluminum with pyramid surface covered with gray golf-ball paint, replacing dirty carpets and rubber mats. Mud-guards are very full and are joined to the frame or body; aluminum aprons extend between the frame and running boards, so that it is almost impossible for mud to splash upon the passengers. The pan underneath stretches unbroken from the front cross member of the frame to within twenty inches of the rear axle; this not only keeps the machinery clean, but should have a good effect on the amount of dust raised by the car. There are no unsightly boxes on the running boards; the storage battery has a compartment under the footboard, and the tools under the front seat.

For coloring I prefer gray; it wears well, does not show the dirt, and, though this may seem a little far-fetched, I do not believe it frightens horses like brighter colors do. Upholstering may be in dark red or dark green and should be smooth, except for the roll around the back of the seat. Tufted upholstery is hard to keep clean and has not the business-like look of the other. A cape cart top is indispensable on a car for every-day use, and should be included in the regular price with the lamps and horn.

Throughout this description I have tried to keep in mind that the "perfect car" is to be sold at a moderate price. Of course, the only way to tell the price definitely would be to make the car, but if made in sufficient quantities it would seem that these specifications could be carried out for \$2,750. The market for high-priced cars is uncertain at the best, and varies with every fluctuation of the stock market; and it will grow smaller and smaller as buyers come to see the disadvantages of great weight and over-long wheelbases. On the other hand, there is even now a steady demand for a car such as I have described, and I believe it will grow stronger every year.

#### WHAT BECOMES OF THE POLISHED CHASSIS.

With dozens of highly polished chassis under their eyes, the question is often asked by show patrons as to what becomes of them after the shows. To produce a smooth, mirror-like surface on side frames, cylinders, gear box, and other parts of the mechanical organs of an automobile is a lengthy and costly task, the work in the main being of such a nature that machinery can only be used in a very limited degree. The utility of the mirror polish ceases with the exhibition, special show chassis—unless they are needed for other exhibitions or salesrooms—being sent back to the works to have their polish removed. The chassis is entirely taken to pieces, and each part submitted to sand blast treatment, after which it is painted and finished in regulation style. The smooth, glossy surface of the show machine makes it almost impossible to apply paint satisfactorily; consequently the car must be robbed of all its glister before it can be given the protective coats of paint with which it will enter into active service.

The buying public demands the opportunity of examining every mechanical part of a car in detail, a fact which is clearly recognized by manufacturers, who do their utmost to educate the unlearned. But as mirror polishing is only labor wasted, it is a pity that fashion should still demand it.

## LETTERS INTERESTING AND INSTRUCTIVE

### MORE CORRECTIONS ON BATTERY CONNECTIONS.

Editor THE AUTOMOBILE:

[976.]—In your answer to letter No. 921, you say that the No. 2 method of connecting up cells, as shown in cut, has the disadvantage of reducing the voltage at the expense of the current, and thereby greatly shortening the life of the battery. The life of the battery is dependent on the amount of current and the rapidity within certain limits with which it is taken from the battery. The amount of current is dependent on the voltage and the resistance of the circuit. The resistance of the coil part of the circuit is so great as compared to the whole that the circuit resistance is practically the same whether there is one set of four cells in the circuit or two sets (in parallel), and the voltage in the two cases would be the same, hence the amount of current would be the same in each case.

The life of the cells then would really be increased somewhat instead of diminished, because the current would be divided between the two sets, so that it would draw only half as fast from each set while the cells were at work. In my own practice I use twenty cells hooked up with two fives on a side.

W. G. BLISH.

Niles, Mich.

While being entirely in accord with everything you have said in the foregoing letter, we are of the opinion that the statement which caught your attention is substantially correct. If not wholly so, at least in the sense in which it was intended and, we believe, generally understood. Induction coils as generally employed on automobiles are wound to operate on a fraction of an ampere, more or less, at six volts. It was not our intention to have it understood that connecting two sets of four cells in multiple was detrimental, for, as you state, it is a matter of common knowledge that increasing the current by placing two or more sets in parallel connection increases the life of the battery. But no matter how many sets of four are placed in multiple, the voltage will remain the same and the *voltage of four dry cells* is not sufficient to satisfactorily operate a six-volt coil, except when the cells are brand new, and not always then. Six cells are preferable and the sense intended to be conveyed was that it was not practical to run on four even though two sets were placed in multiple. We must admit the language was ambiguous.

### QUERIES CONCERNING STEAM TURBINES.

Editor THE AUTOMOBILE:

[968.]—Please answer the following questions through the "Letters Interesting and Instructive" department.

1. Can a 23-inch boiler operate a small turbine with a steam pressure of 400 pounds?

2. Would a small turbine operate a motor boat successfully?

3. Can you give me the address of any concern manufacturing steam turbines?

4. Does any concern manufacture flash boilers and sell them to the trade?

W. & S.

Athol, Mass.

1. If the steam consumption of the turbine be proportioned to that of the generator, there appears to be no reason why it should not operate successfully, though we have never heard of such a high pressure being employed and are under the impression that its use would be practically impossible. Pressures favored by current practice in turbine design range from 70 to 80 pounds, and with such a drop as this, the generator you mention would hardly be capable of supplying sufficient steam.

2. Turbines were first proven successful on small vessels such as torpedo boats, so there seems to be no reason why this should not be the case with a motor boat. It would probably be necessary to use gearing to keep the speed down, as such a small unit as you would employ would have an excessive r.p.m. rate, 4,000 or more. A special propeller would also be necessary.

3. Westinghouse Machine Company, Pittsburgh, Pa.; De Laval Company, Trenton, N. J.

4. You will find the announcements of such makers in our advertising pages.

### WANTED, A GOOD GUN-METAL FINISH FOR LAMPS.

Editor THE AUTOMOBILE:

[969.]—Believing that it would be of great interest to many of your readers, I would like to ask if you can offer, through your columns, a formula for gun-metal finish for lamps, and the like. This finish gives a pleasing appearance, and saves a lot of drudgery in the way of polishing.

W. P. ANTHONY.

Eddystone, Pa.

A steel-blue color may be produced on brass by dipping it into a dilute solution of chloride of arsenic, which should be boiling at the time. Or 10 parts of chloride of antimony dissolved in 200 parts of water, in which 30 parts of pure hydrochloric acid have been dissolved. The articles should be dipped until well blued and then washed in clean water and dried in warm sawdust. Black may be produced by coating with a solution of platinum or auric chloride mixed with nitrate of tin. Neither of these is a gun-metal finish, but could probably be made equally attractive and would serve the end in view. The brass should be thoroughly cleaned before undertaking any of these operations, and to do this it would be necessary to dip the articles in a pickling solution composed of one part sulphuric acid to 10 parts water, and washing well before proceeding further. Most of these special finishes are, however, electrolytic, requiring the facilities and skill of an electro-plater to put them on permanently, and we doubt very much if amateur efforts would be entirely a thing of beauty or a joy for any great length of time.

### WHICH COMES OUT AHEAD—DOG OR MAN?

Editor THE AUTOMOBILE:

[970.]—I have a few questions for "Letters Interesting and Instructive," as follows:

1. What do you recommend for a non-freezing solution? Would alcohol and water do, without glycerine? If so, what test should the mixture show? Would not such a mixture be less objectionable than one with the glycerine in a car that never runs very hot in the warmest weather?

2. What do you recommend as a brass cleaner and polisher; something that can be easily obtained when none of the prepared solutions are at hand?

3. Would a gill of dry powdered graphite thrown into a planetary gear transmission and sufficient oil added to make a thin paste of it be harmful? I notice that some who recommend the use of graphite seem to advise its use sparingly. Would there be danger of its solidifying or otherwise doing damage in a gear as above?

4. Would some one kindly describe what is most liable to happen when a large dog is run over by a small runabout? While few of us would care to know about this from actual experience, the time is liable to come to any of us any day when driving, when we are called upon to decide immediately between dog and ditch, and as we can tell something about what to expect of the ditch, judging from the size of it, together with our speed, I should like to know something about the dog, from some one else's experience, though perhaps sad it may be to relate.

FRED. D. CLARK.

Prattsburgh, N. Y.

1. For a car which never runs overwarm and on which there is no risk of undue loss from either evaporation or steaming, probably a wood alcohol solution is the best. A 10 per cent solution with water will not freeze down to 15 degrees F.; 15 per cent, 5 degrees F.; 20 per cent, 2 degrees F.; 25 per cent, 0 F. With glycerine and water, solutions of the same percentages give freezing limits of 20, 15, 8 and 5 degrees F., while with calcium chloride these are lowered to 15, 5, 0 and - 0 F., so that the last-named is probably the most efficient for very low temperatures. Both wood alcohol and glycerine affect rubber so that the flexible joints in the circulating system should be watched for disintegration from time to time, but this is not as great a drawback as the risk of forming deposits in the radiator and waterjackets due to the use of calcium chloride, though this is only apt to occur where the water comes to a boil.

2. A saturated solution of table salt in vinegar is a most effective cleanser for brass. Only the liquid should be rubbed

on, as grains of salt carried on the cleaning rag will scratch the metal. This should be thoroughly washed off in warm water and followed by the application of some cleansing paste, or lacking this a coating of vaseline or lubricating oil will serve to keep the lamp bright, though it will also catch a great deal of dust.

3. It would not be advisable to use graphite or any other paste in a small planetary change-speed gear. Any heavy grease or "dope" would lower the efficiency of the gear considerably by creating a great deal of unnecessary resistance to the turning of the pinions in the confined space. Only thin oil such as is ordinarily used for cylinder lubrication should be employed. Makers of such cars usually specify this particularly in their instructions.

4. Though lacking in the requisite personal experience to give a definite answer to your last query, we should certainly have a decided preference for immediate assassination of the dog, no matter how large, rather than try conclusions with any ditch, no matter how small. The effect of taking the ditch is quite well known, as you infer, and it is particularly on that account that we should prefer damaging the dog, as the result, though uncertain, would doubtless be far less harmful. In the Vanderbilt Cup race of two years ago, Lytle in the Pope-Toledo smeared a good-sized Newfoundland over a mile or more of the Jericho Turnpike. But his speed was probably something like eighty miles an hour and the impact did not disturb the driver in the slightest, to judge from appearances. If there is the slightest time for consideration, we should exert every effort to have one front wheel do the business of killing the animal, as was most neatly accomplished by a French driver in a road race a few years ago. He saw the dog in time and probably might have avoided him, but chose to put him under the left front wheel of his car, which was done much as a skilled marksman would hit a bullseye. Neither the driver nor the dog was disturbed in the slightest, for the latter ended his existence so quickly and peacefully as not to know what had happened to him. Both these occurrences were at high speeds, but we should never hesitate to hit the dog rather than take the ditch. The chief danger to be feared is derangement of the steering gear through the collision, and running over the dog neatly by getting him under the wheel is the easiest way to avoid this. Unless the dog was big enough to upset the runabout, or the driver lost control, no unpleasant results should follow, except to the dog.

#### CAUSE OF A MOST MYSTERIOUS TROUBLE.

Editor THE AUTOMOBILE:

[971.]—The car that I have charge of carries a four-cylinder engine, and some four weeks ago we were overtaken with a knock in the engine. The car was taken to a garage and the rollers on the uplifts were found worn and replaced with new ones, and our knock is gone; but since then we have been troubled with our engine heating. I will tell you just what we have done to locate the cause, all to no avail. We tore down the engine and removed all carbon from the pistons and cylinders, and then drove the car ten or twelve miles, and it was just the same; that is, when we shut off the electricity the engine made several revolutions and then would run backwards two or three revolutions before it would stop. We then looked at the water pump, and the circulation is O. K.; there is no short-circuit anywhere, cylinders are properly lubricated, and the timing is perfect, and we are running on the same mixture that we used before it began to heat, and still it is heating.

Will you kindly let me know what your experienced opinion is in regard to this matter, and as I am just getting into the auto business, it would be a very much appreciated help to me to be able to locate this trouble for my employer.

A. S. BURKE.

Westfield, Mass.

It strikes us as somewhat queer that the trouble having developed immediately after new rollers were put in place, its connection with the latter was never thought of. The fitting of these new parts without in any manner altering the remaining parts with which they work has naturally served to throw the valve timing all out of adjustment. This is evident from the fact that the motor will run backward for several revolutions, as the average automobile motor is not designed to run in more than one direction, usually clockwise. The cams are not ordinarily

designed to permit it to run in the reverse direction, and we doubt if you will find your motor is capable of doing this when in proper adjustment. Assuming the mixture and other adjustments to be correct, it looks as if the exhaust valve were closing too early, thus imprisoning some of the burnt charge and causing the motor to overheat.

#### ALCOHOL AND KEROSENE AS EMERGENCY FUELS.

Editor THE AUTOMOBILE:

[972.]—Kindly let me know, through "Letters Interesting and Instructive," if a motor car can be run on alcohol or kerosene oil if you run out of gasoline.

H. MCKAY.

Philadelphia, Pa.

Either of these fuels may be used in an automobile motor in an emergency, and by creating as far as possible favorable conditions for their employment, the results will be practically as satisfactory as with gasoline, barring the item of consumption, which will be much greater, particularly in the case of alcohol. If the motor be still warm when the lack of further gasoline is discovered, there should be no great difficulty in getting it under way on either kerosene or alcohol, but if allowed to get cold it will not start as easily and it will probably be necessary to warm the carbureter by wrapping it in cloths dipped in hot water, or by filling the cooling system with hot water. The latter should also be so arranged as to have the motor run much hotter than ordinarily, otherwise the amount of power developed on either of these fuels is not apt to be satisfactory, as owing to their heavier nature, more heat is required to vaporize them. The fan might be stopped or other means taken to raise the temperature, as the cooling water should be allowed to almost reach the boiling point in order to obtain the best results.

#### WANTED—AN AUTOMATIC LEAK STOPPER.

Editor THE AUTOMOBILE:

[973.]—Do you know of anything on the market that will stop a radiator that leaks? Anything that can be put in with the water. If you do, kindly let me know, and oblige.

Constantine, Mich.

WALTER H. CORNELIUS.

Considering the first part of your question alone, we should say "Solder," but noting the remainder of it, hardly think this answers your query satisfactorily, as lead and water will not mix very well. In case of emergency, a handful of bran will reduce the leak to such proportions that the car may be run without danger, or where very small, will stop it altogether, but aside from this we do not know of any special preparation on the market for this purpose, and should hardly recommend its use, if there were one, as such a repair is merely a makeshift of a very crude type. The only thing to do with a leaky radiator is to have it properly repaired as soon as possible after the leak is discovered in order to prevent further damage, and as it takes a skilled workman to repair a radiator it is advisable not to entrust it to the first tinker as a bungler with the soldering copper can do untold damage to a valuable radiator.

#### WHAT IS THE TROUBLE WITH THIS COIL?

Editor THE AUTOMOBILE:

[974.]—Can you help me out on the following trouble, with an answer through your valuable paper? I have a two-cylinder spark coil which is missing sparks a great deal. I have bought new sparking points, both tremblers and screws. But it still misses. It is a La Coste coil. No matter how I adjust it, it still misses. Could there be anything the matter with the inside of the coil?

New York City.

F. JACKSON.

There may be considerable the matter with the "insides" of the coil. From the symptoms you give, it would appear that the connections between the ends of the coil, most probably the primary, and the binding posts on the outside of the case, are broken, but not entirely severed, being kept in contact more or less by the insulation, but the jarring of the car knocks them apart at times, which would explain the missing. They resunie

action when the wires jar back again into contact, and the number of times that this will occur as well as the length of time that wires will remain in this condition, is amazing, as we have had occasion to learn from personal experience. Such a break in the secondary winding would not be productive of similar symptoms as the current would jump the break and the effect would be merely that of an extra spark gap. It is also possible that the secondary has been burned out and the current only manages to get through occasionally. The thing to do is to consult the coil maker.

#### HOW ARE TWO-CYCLE MAIN BEARINGS OILED?

Editor THE AUTOMOBILE:

[975.]—I am a constant reader of "The Automobile," and I take the liberty to ask a question through your "Letters Interesting and Instructive." What is the method in general use concerning the lubrication of the crankpin and piston pin of a two-cycle engine of the automobile type? What would be a conservative estimate of the B. H. P. of a 4 x 4 two-cycle three-cylinder automobile engine, ordinary compression at 700 r. p. m.? G. P. VANCE.  
Elwin, Ill.

Mechanical force-feed lubricators with feeds led directly to the bearings and sight-glasses on the dashboard are generally employed for this purpose on two-cycle cars, the same as on others. There is always a small amount of oil in the bottom of the crankcase as in the four-cycle, although the quantity is closely limited owing to the restricted dimensions of this essential. This splashes the crankpin and the sides of the piston that travels below the lower edge of the cylinder; the piston works the oil up and down between itself and the cylinder walls and sufficient of the oil finds its way into the piston pin bearings. A conservative estimate would be 12 to 15 horsepower.

#### LENGTHENING THE WHEELBASE OF A CAR.

Editor THE AUTOMOBILE:

[976.]—I would like your opinion about lengthening the wheelbase of my Maxwell runabout. I am thinking of putting two full elliptic springs in front and clamping them to the frame back of the radiator. Would the car ride enough easier to pay for the change? I would like to hear from anybody who has made this change. MAXWELL.  
Crestline, O.

The advisability of making such a change depends largely upon the manner in which it is done, as it naturally follows that increasing the wheelbase of such a short car will make it ride much more comfortably. Doubtless there are some readers of THE AUTOMOBILE who can throw more definite light on the matter by giving their personal experience.

#### WHO INVENTED THE GASOLINE ENGINE?

Editor THE AUTOMOBILE:

[977.]—Wish to ask you who invented gasoline engines. A. M. PAINTER, M.D.  
Parsons, Kansas.

Beau de Rochas is credited with being the first to propose what is known as the compression type of internal combustion motor, making the use of gasoline possible, and Otto was the first to develop it practically, though all engines at that time were run on gas. It is generally conceded that Gottlieb Daimler was the first to successfully employ a liquid fuel in a motor of this kind.

#### WHO CAN FURNISH THESE MATERIALS?

Editor THE AUTOMOBILE:

[978.]—I have been referred to you regarding parties who furnish blue prints or castings for gasoline engines of the automobile type. I want to buy either a blue print for an engine of 90-100 horsepower or the castings for same in the rough. Also, of whom can I get chassis, bodies, etc.? UNIVERSITY OF ILLINOIS.  
Pontiao, Ill.

We do not know to whom to refer you for the materials you desire, but doubtless our advertising columns, or some of our readers to whose notice your letter comes, may be able to help you out by furnishing the required information.

#### FORMULAE FOR SOLDERING ALUMINUM.

Editor THE AUTOMOBILE:

[979.]—Kindly give me a formula for soldering aluminum. GEORGE MALLEN.  
Chicago.

Tin 30 parts, zinc 7 parts, aluminum 3-4 part, manganese 1-10 part; or, using chromium with manganese, tin 30 parts, zinc 8 parts, aluminum 1 part, manganese q. s., chromium 1-16 part, the solder being prepared by fusing together the above-named materials. This is a formula on which a patent has been granted in this country but a short time ago. There are a great many others of differing natures extant, but as there is a firm now manufacturing a specially prepared aluminum solder under their own trade name and by a special process, it would doubtless be far better for anyone requiring a small quantity to purchase it, as the materials required would be expensive and difficult to procure. You will find the announcement of the concern in question in our advertising pages.

#### POWER REQUIRED TO TURN A MOTOR OVER.

Editor THE AUTOMOBILE:

[980.]—I wish to call your attention to an error in the answer to H. C. Arnold (951) which appeared in "The Automobile," issue of November 7.

One horsepower is that power which will raise 550 pounds one foot per second, 33,000 pounds one foot per minute, or 33 pounds one foot in 1-1000 of a minute.

If 2.5 horsepower is consumed in turning an engine under full load it requires the continuous application of 2.5 horsepower to keep the engine moving regardless of the length of time.

The power consumed per revolution should be expressed in foot pounds. One horsepower equals 33 foot pounds per 1-1000 of a minute, or the time required for a revolution, consequently 33 x 2.5 or 82.5 foot pounds are required to make one revolution of the motor.

In experimenting with the Adams-Farwell revolving motor (which is controlled by means of variable compression) the writer has discovered that when using the engine for a brake, an increase in the compression decreases the braking effect of the motor.

This disproves the popular theory that the braking effect of a motor is due chiefly to compression. The fact is, that the gas is heated by compression and expands on the down stroke of the piston giving back a trifle more power than was consumed in compressing it, as long as the engine retains its heat.

When a motor is turned over by hand time is allowed for some leakage past valves and pistons and some power is consumed in friction so that no accurate idea can be gained of the power given back to the piston by the compressed gas.

The braking effect is due to suction, as can easily be demonstrated with any motor controlled by throttle. Closing the throttle increases the braking effect of the motor; whereas, the opposite would be true if increased compression meant increased braking effect.

This suction and braking effect is also present in all throttling engines when running under their own power with a partially closed throttle.

Dubuque, Ia. THE ALCOHOL COMPANY,  
GLENN MUFFLY.

#### THINKS GOOD CHAUFFEURS NOT IN DEMAND.

Editor THE AUTOMOBILE:

[981.]—I notice that "Experienced," in letter No. 916, page 428, issue of September 26, says that, taken as a whole, he has quite some faults to find with the automobile game. He is certainly far from wrong in many respects, and while not employed in the same capacities as "Experienced," yet, from a chauffeur's viewpoint, let me cite instances as I have found them.

It has been said the automobile field offers splendid opportunities for young men, and that good chauffeurs are in demand, but this statement is evidently misleading; it certainly has been with me. I find that every place I have made application that they need no drivers. I grew tired of chasing and advertised, answered "ad" after "ad," but to no advantage, and yet I held references as good, if not better, than most fellows hold. But while I do not know how true, however, I have been told on good authority that the recommend of a friend is better than all written references, and I am about ready to believe it.

Now I don't pretend that I know everything about the automobile field, but I do claim that my experience on the road has taught me more practical pointers than could ever be gained in a shop or school. It is not for the mere pleasure of driving that I chose automobile work, but as a means of earning a livelihood, and yet to me it seems that I have chosen the wrong calling. G. F. JACKSON.  
Roselle Park, N. J.

TYPICAL BRIDGE IN HEART OF THE CATSKILLS, WHICH PRESENT PICTURESQUE SCENERY WORTH STRUGGLING TO REACH.

### AUTOMOBILE'S UTILITY.

In the early days of automobil- ing it was a source of satisfaction to have the motor-driven vehicle proceed at a reasonable pace over the best of highways. Nowadays traveling of the most extra- ordinary sort is asked and invariably the most difficult conditions are successfully coped with, even though it be over mere apologies for roads and often no roads at all.

Recently H. A. Grant made a hunting trip which took him and his companions into the heart of the Catskill Mountains. A 36-horsepower Maxwell was converted into a runabout, and the car supplied ample power for all necessities encountered during the trying trip, a good part of the 600 miles consisting of mighty poor traveling surface, and at times the going was sufficient to tax even the proverbial Western

STARTING UP CROSS MOUNTAIN FOR HARD CLIMB.

broncho that can ascend a mountainside.

Included was a climb of Cross Mountain, which to the best knowledge of Mr. Grant had never been successfully attempted before by an automobile.

Finally the exploring craft made its way into the woods just as far as its pilot could drive it. It would have been necessary to blaze a path with the swinging of axes before any further progress could be accomplished.

When one goes out of the beaten path he must needs keep in mind a source of replenishment for his gasoline tank, for the product of the Standard trust is still a requisite for most satisfactory progress. However, with the automobile appearing nowadays in most unexpected quarters, the backwoods storekeeper generally has gasoline for sale.

IN THE HEART OF THE WOODS, WHERE FURTHER PROGRESS WAS MADE IMPOSSIBLE BY DENSE FOREST AND ABSENCE OF ROAD.

## AN UNBIASED COMPARISON OF THE FOUR AND SIX

By GLENN MUFFLY, THE ADAMS COMPANY.

BEING interested in the manufacture of the only five-cylinder motors on the market, we are in position to give an unbiased opinion on the relative merits of four and six-cylinder motors. The recent articles by F. B. Stearns and the Winton Motor Carriage Company have interested us to the extent that we hereby volunteer a few remarks which may be new to some readers. Let it be said before starting that any number of cylinders up to nine or ten could be used on our revolving motor without addition to the electrical or valve-operating devices. We chose five as the least number of cylinders on which the power strokes overlap.

The principal weak points of the ordinary four-cylinder motor are that the power strokes do not overlap, and at the very time that no power is being generated, the flywheel must be robbed of enough inertia to stop and start all of the pistons. Also the maximum compression comes at a point where the force of the preceding explosion is entirely spent. The six overcomes these difficulties, but loses a point at the same time. In the four-cylinder the pistons are accelerated by the crankshaft at the time of highest explosive pressure, and return part of this inertia to the crankshaft during the latter half of the stroke, as the explosive pressure diminishes. This means that the power transmitted to the crankshaft of the four-cylinder is more uniformly distributed over the effective part of the explosion stroke than in the six. However, the fact still remains that during a brief period of time (about 1-10 of a revolution, or 1-50 of a second at 300 r.p.m.) no power is being generated by the four-cylinder motor. This is not serious, except when taken in conjunction with the above fact that during this interval between power strokes an extra load is imposed upon the flywheel in the form of inertia and compression.

That the weakness of the four-cylinder motor is due to the power consumed in overcoming inertia, and not to the interval between effective power strokes, is proven by the fact that the old Adams-Farwell three-cylinder motor, not having any reciprocating parts, will pull a load at a slower motor speed than is possible with the usual four-cylinder type, in spite of the longer interval between explosions. More power is wasted in overcoming inertia in the six-cylinder type, but only two pistons stop at the same time, and that, while an explosion is taking place, so that the six runs smoother than the four. The difference is not noticeable except at slow speeds, but as slow motor speed is greatly to be desired the six is superior to the four.

Again, it can be shown that considerable power is consumed in overcoming inertia, as the five-cylinder Adams-Farwell will pull a load at a slower motor speed than is possible with the ordinary six-cylinder. The advantage gained by eliminating reciprocating parts overbalances the difference in the frequency of impulses. The revolving motor is also aided by a much heavier flywheel, as practically the entire motor revolves about a stationary shaft. A cylinder of a given size will develop the same amount of power whether working alone or in a set of six, other conditions being equal. In fact, the more frequent

impulses being conducive to steady running should increase the efficiency of the multiple-cylinder motor. Theory and practice do not always agree, chiefly because the theory is not complete.

Here are a few points to be considered by the advocate of many cylinders: The power from the cylinder next to the load is transmitted through two bends in the crankshaft and one bearing; the power from the next cylinder is transmitted through six bends and two bearings; the third through ten bends and three bearings; the sixth cylinder must transmit its power through twenty-two bends and six bearings. It is not hard to conceive of a motor so long that the power from the cylinder farthest from the load, would be entirely consumed in transmission. In four-cylinder stationary power-plants it is customary to apply the load to the middle of the crankshaft. A six-cylinder crankshaft with the driving pulley on one end would call forth severe criticism from designers of stationary engines, who must consider efficiency more carefully than do makers of automobile motors.

It is claimed that the constant suction of the six-cylinder motor aids carburetion. This may be so, but constant suction means that a partial vacuum is constantly maintained in the intake manifold, thus reducing the charge admitted to the cylinders and retarding the piston on the suction stroke. In the four-cylinder motor, the gas in the inlet pipe attains considerable velocity before the end of the suction stroke, and as the piston speed decreases, this velocity aids in ramming the cylinder full of gas. On the other hand, as the end of the suction stroke is approached in the six, another cylinder starts drawing in a charge, thus reducing the pressure within the manifold in spite of designs calculated to prevent it. Some six-cylinder motors have been found to give better results when equipped with two carbureters to overcome this difficulty.

A defender of the six-cylinder type says: "Radiating surface increases as the square, whereas cylinder volume—horsepower—increases as the cube." This calls attention to the fact that more heat units are lost through the cylinder walls of the six than through the walls of a four-cylinder of equal horsepower. As timing gears are set by some one cylinder, we do not see what difference it would make to the mechanic how many cylinders the motor had. As for grinding valves, cleaning spark plugs and looking for knocks or short-circuits, there is no reason why a four-cylinder man could not do the work on a six, but, of course, 50 per cent. more time would be required. We heartily agree with F. B. Stearns in his statement that passengers and motor should be carried between the axles, but think his comparison of a four-cylinder gasoline motor to a four-cylinder steam engine a little overdrawn. We believe, however, that a four-cylinder motor with a liberal flywheel is preferable to the six, unless it is for a high-powered machine with small seating capacity. Personal prejudice may influence the writer in favor of the revolving five-cylinder, but probably there is some reason for being prejudiced in favor of a motor that rivals the six in constant torque and the single-cylinder in simplicity.

## THE FOUR CYLINDER MOTOR, THE ENDURING TYPE

By C. F. REDDEN, STUDEBAKER BROS. COMPANY.

THERE has been recently a lively discussion by the advocates of four and six-cylinder engines. It is interesting to trace the development of the modern internal-cumbustion motor from the original single-cylinder to the multiple-cylinder of the present day. When the automobile was in its infancy, the single-cylinder motor was popular; first, because of its simplicity, and, second, because it was easy to manufacture and most economical to run.

This type, while highly satisfactory from the standpoint of reliability, was objectionable on account of excessive vibration. With the advent of the two-cylinder motor a large amount of this vibration was eliminated, but not all. Both the three-cylinder and four-cylinder motors were built, the three-cylinder surviving but a very short time, not so much on account of imperfect balance as on account of difficulty of manufacture. The four-

cylinder motor has become standard because it produces a smooth-running engine with a minimum of complications. The six-cylinder advocate points out that if the two-cylinder is better than the one and the four better than the two, that it is only logical the six should be better than the four, but this does not necessarily follow. Reasoning this way, it might be pointed out that the eight or twelve cylinder is better than the six, but in the manufacturing of every article a certain standard is attained which practice and experience have shown to be most satisfactory, and beyond which no great advantage is obtainable.

It seems to me that the logical way to look at the matter is that the power required necessarily governs the number of cylinders. It has been proven by experience, and designers are generally

agreed, that a 5x5 or a 5 1-2x6-inch cylinder is about the maximum that it is advisable to make. Therefore, for cars up to 40 or even 50 horsepower the four-cylinder motor fulfills every requirement, while for an engine rated at, say 70 horsepower, it is perhaps advisable, though not necessary, to increase the number of cylinders in order that each separate unit may not be too large. I am fully convinced that the standard touring car of the present time, as well as the future, will be fitted with a four-cylinder motor of approximately 40 horsepower. This type of motor car will appeal to a large conservative class of buyers with the wish to use their cars as distinct utilities and who are not affected by fad or fancy, and who are also quite averse to paying for the needless carrying of weight or burning of fuel.

## EVOLUTION FROM A MOTORETTE TO A SIX-CYLINDER

By DAVID FERGUSON, CHIEF ENGINEER OF THE GEORGE N. PIERCE COMPANY

**A**N honest tale speaks best being plainly told. Briefly, the history of Pierce construction is as follows: In 1900 the Pan-American Fair year, we showed for the first time at the Buffalo Fair, and in the first Madison Square Garden Show, what we then termed a motorette. It was fitted with a 2 3/4-horsepower DeDion motor, of the single-cylinder vertical type, carried in the rear. The change-speed transmission was of the planetary type, and then spur geared driven to the axle.

Our next type was called the stanhope model, and these we then made 3 1/2, 5, 6, and 8 horsepower. They were all of the single-cylinder motor style, with the motor in the rear, the making of which we have since abandoned.

Five years ago we produced a 15-horsepower car, with a vertical motor in front, following the then French practice which had just come into vogue. This car had clash gears, and was bevel driven. The bevel gear drive, which is new to some makers, has been used by us ever since that time.

Four years ago we produced our first four-cylinder "Great Arrow" car, and still continue to produce that type. In 1906 the first six-cylinder "Great Arrows" were produced. Every type car we have ever made has had, for convenience sake, the change-speed lever on the steering column, the only side lever to be found on Pierce cars is that used for the emergency brake.

I strongly advocate, as the result of experience, the use of the six-cylinder car because it is the ideal car for the man who wants the best, and who is willing to pay for it. Of course, for the man who wants to save money in the purchase of his car the four-cylinder will fill the bill. There is no question in my mind but what the six-cylinder car, as I have said before, is perfectly ideal. It is quiet, easy on the transmission, easy on the tires,

and, because it can be nearly always run on the top gear, we fit it with only three speeds. Three speeds is enough because the direct drive is on the high. There is very little use or need for the low speed anywhere, except in mountain climbing.

Two and four-cycle motors have always produced satisfactory results. The six-cycle motor did not produce very good results in stationary practice in England, according to my observations. A cylinder-fired hydro-carbon motor is really a heat motor, and the conservation of heat is the conservation of energy. A six-cycle motor, with its air cooling charge, might cool a motor too much and lower the temperature of the cooling water below 100 degrees, which is impracticable.

I should regard the gas turbine as the final and last word in gas engine practice, because all the cycle phases are reached in that practice. In the present state of the art, the six-cylinder motor is better than any other multiple type, excepting some other multiple having six as its factor, such as twelve, eighteen, twenty-four, thirty, and, finally, thirty-six, the full degrees of the circle. Anything above six-cylinder is too long for an automobile chassis.

Thirty-six-inch wheels and tires seem now to be the ultimate thing, being the happy medium between the twenty-eight-inch bicycle wheel and the forty-four-inch carriage wheel, for tests have shown that any further increase in the size of wheels show a gain only measured by a decimal point.

The forward position of the motor on the chassis in line with the front axle has the merit of distributing the weight between the two axles and also makes for easy steering, and, hence, I do not see any chance for a further shifting about of the power plant from its present well-established position.

## PREDICTS SIX CYLINDERS FOR ALL BIG CARS

**T**HE six-cylinder automobile is destined to become a predominant type for high-power machines, according to H. H. Franklin, who gives his opinion as follows:

"In two years practically all automobiles over 40 horsepower will be of the six-cylinder type. Below that horsepower they will be of the four-cylinder type, except in the cheap grade automobiles, which will employ one and two-cylinder motors.

"This does not mean, as it might first appear, that the six-cylinder automobile is going to predominate. The predominating automobile will be of small and of light weight and its horsepower will be under 40.

"The six-cylinder automobile, properly built and designed, is, power for power, lighter and cheaper to build than the four-cylinder. It is easier on tires, easier on the transmission and all the mechanism. Because of the smaller diameter of the flywheel there is more ground clearance. The advantage of this, however, is probably offset by the necessary increase in the wheelbase. The six-cylinder automobile, power for power, is more econom-

ical than the four-cylinder. The six-cylinder automobile as it is now being made is too big and too heavy. Manufacturers have added to the already excessive power and weight. This is a great mistake.

"What is wanted is high power with light weight, not high power with excessive weight and bulkiness. The six-cylinder construction offers just what is wanted in that high power can be obtained with less weight and less expense than with four cylinders, but the manufacturers have not done this.

"I predict that within two years the weight of six-cylinder automobiles will have been greatly reduced and a 40 six-cylinder water-cooled automobile will weigh about three thousand pounds, and in due time even less than that. The Franklin air-cooled automobile of 42 horsepower weighs only 2,500 pounds.

"The six-cylinder automobile is very satisfactory to operate. It has that pleasant, smooth-feeling pull, with an entire absence of jar or jerk. It is a better machine to run slowly, due to the six impulses or steady torque, and it requires vastly less work on the part of the driver, owing to the infrequent necessity for gear-changing."

## WHAT SOME OF THE AUTO CLUBS ARE DOING

### OHIO'S ENTERPRISING CLUB AT CHILLICOTHE.

CHILICOTHE, O., Nov. 18.—One of the liveliest and most progressive automobile clubs in the Middle West is that organized at Chillicothe a short time ago. It has already a very large membership and is rapidly growing. The intention is to give a series of runs during the coming season. The first of these proved most successful, fifteen cars being entered. Silver cups were awarded for the first and second prize, the first prize being captured by Walter Barret with a Reo, and the second by Joseph Atwell with a Pope-Toledo. The run was followed by an informal luncheon at the club's headquarters.

As Chillicothe is the home of the Logan Construction Company, there were naturally a number of Logans in the tour, as will be seen in the accompanying photograph.

The idea of the club in giving these tours is not to attain neck-break speed, or to impose conditions which would make the tours irksome to the contestants. It is intended to make the conditions such that the tours will be pleasant excursions and are designed more to bring the autoists of Southern Ohio into close and

### ANNUAL ELECTION OF THE CHICAGO A. C.

CHICAGO, Nov. 18.—There was no opposition ticket in the field in the recent election of the Chicago Automobile Club, and therefore these were the unanimous selections of the members: President, Ira M. Cobe; first vice-president, F. H. Pietsch; second vice-president, T. J. Hyman; secretary, N. H. Van Sicklen; treasurer, C. E. Gregory; directors, John Farson, Claude Seymour, T. J. Koehler, F. D. Countess, A. J. Banta, and Walden W. Shaw.

During the past year 105 active members have been added to the membership list, giving a total of 582 members, 478 of which are active, 96 non-resident, 5 life, and 3 honorary. The membership dues were increased from \$50 to \$60 a year, the initiation fee being left at \$100. There is agitation for an auxiliary membership, but the impression prevails that there would be considerable difficulty in working out a successful scheme of this sort.

It is possible that the annual banquet of the Chicago Automobile Trades Association, scheduled to take place the evening before the opening of the Chicago show, may be held in the clubhouse of the Chicago Automobile Club. It is a question,

HOW THE CARS LINED UP FOR THE FIRST TOUR OF THE CHILICOTHE AUTOMOBILE CLUB.

friendly association than to impose straining conditions on the cars entered. It is required, of course, that all cars be driven by the tourers, and no professional chauffeurs are permitted in any of the contests, the idea being to enable the car owner to demonstrate his proficiency at the wheel.

### A. C. OF WASHINGTON WANTS BIG MEMBERSHIP.

WASHINGTON, D. C., Nov. 18.—The social season of the Automobile Club of Washington was auspiciously opened Saturday evening with a smoker at the clubhouse on the Brightwood road. Several hundred members and their friends enjoyed a good vaudeville program arranged by the house committee. The committee has a number of good things in hand for the members during the next few weeks.

A meeting of the club was held Wednesday evening, November 13, and steps were taken to reduce the initiation fee to \$10, and the yearly dues to the same figure. By this means it is hoped to take a hundred or more new members. The club is in good condition and is wielding considerable influence in local automobile affairs. The social season promises to be unusually active this winter. The opening of Congress a few weeks hence brings to Washington an increasing number of autoists among the statesmen, a large proportion of whom own cars.

however, as to whether the large attendance could be accommodated in the grill room of the club. The board of directors has tendered the use of the club house to the trade association, and the matter of holding the banquet there will be settled in a few days.

### YORK (PA.) ENTERTAINS TOURING PARTIES.

YORK, PA., Nov. 18.—Since the announcement has been made that the Motor Club of Harrisburg will hold another endurance run next spring, local autoists are wideawake and have proposed a joint run with the Capital City enthusiasts. The run will be held early in the spring, and from present indications promises to be a bigger success than last May.

Although the weather is just a trifle cool, it has no effect upon the autoists in this locality. Touring parties from all parts of the East continue to stop in this city on their runs to and from the battlefield at Gettysburg, and nearly every night sees a half dozen or so big touring cars stored in the local garages.

During the past week scores of York autoists attended the annual show at Philadelphia. The Quaker City display was voted a grand success by the local contingent, and naturally more than ordinary interest was centered in the exhibition of the York Motor Car Company, makers of the Pullman cars. The Pull-

W. A. Wishart and party of Oakland, Cal., in an Acme Car, in front of the Hotel Potter, at Santa Barbara.

man display and demonstration cars were returned over the road to York yesterday and will probably be sent to the Baltimore show.

#### DELAWARE A. A. IS INCREASING IN MEMBERSHIP.

WILMINGTON, DEL., Nov. 18.—The Delaware Automobile Association has complained to the authorities about glass in the streets of Wilmington, caused by milkmen allowing bottles to fall and break. The association contemplates requesting the Wilmington & Kennett Turnpike Co. to sprinkle its roadway in summer. The association is making arrangements to get out a road book, which will show all of the roads in this section and will contain much other information, including the names of the members.

Arrangements are being made to place signposts at road intersections in the vicinity of Wilmington, which are now lacking at many points. The association now has a membership which includes about one-third of the automobile owners in the State, and it is growing.

#### BAY STATE A. A. ESTABLISHES A BILLIARD ROOM.

BOSTON, Nov. 18.—At the monthly meeting of the board of directors of the Bay State Automobile Association held last week, much business pertaining to the organization was considered and transacted. The board took action on several measures which will prove of material value to the organization in the very near future, one of the most important of which was the determination to establish a billiard and pool room. The parlor on the second floor, once known as the ladies' reception room, is now to be turned into headquarters for those who delight in chasing the ivories over the green.

#### "TUESDAY NIGHT" AT THE A. C. OF AMERICA.

NEW YORK, Nov. 19.—The regular Tuesday night at the Automobile Club of America consisted of an interesting illustrated lecture, "The Federation of the World," by Hamilton Holt, managing editor of the *Independent*. Mr. Holt attended the Peace Conference at The Hague and is thoroughly familiar with the subject. Many members attended, not a few of whom participated in the club dinner which preceded the entertainment.

#### DECEMBER 6 ANNUAL DINNER OF L. I. A. C.

BROOKLYN, N. Y., Nov. 18.—The annual dinner and vaudeville show of the Long Island Automobile Club is set for Friday evening, December 6, and all members are requested by Edwin Melvin, chairman of the dinner committee, to keep the date in mind and arrange affairs so as to be able to attend. Detailed information will be made public later. Several notable speakers are expected to attend.

## THE AUTOMOBILE CALENDAR.

### AMERICAN.

#### Shows and Meetings.

- Nov. 30-Dec. 7.—Chicago, Coliseum and First Regt. Armory, Eighth Annual National Automobile Show, and First Annual Commercial Vehicle Show, National Association of Automobile Manufacturers.
- Dec. 9-14.....—Detroit, Riverview Park Auditorium, Detroit Automobile Dealers' Association. LeRoy Pelletier, manager.
- Dec. 14-21.....—St. Louis, Mo., Jai Alai Building, Second Annual Auto Show, St. Louis Automobile Manufacturers' and Dealers' Association. D. M. Strauss, manager.
- Dec. 28-Jan. 4.—New York City, Madison Square Garden, Importers' Salon. C. R. Mabley, manager.
- Jan. 14-18.....—Hartford, Conn., Foot Guard Hall, Hartford Automobile Dealers' Association.
- Feb. 1-8.....—Providence, State Armory, Automobile Show. Frank M. Prescott, manager.
- Feb. 10-15.....—Detroit, Light Guard Armory, Tri-State Automobile and Sporting Goods Association, Seventh Annual Show.
- Feb. 17-22.....—Cleveland, Central Armory, Annual Show, Cleveland Automobile Dealers' Association. George Collister, manager.
- Mar. 7-14.....—Boston, Mechanics' Building and Horticultural Hall, Boston Automobile Dealers' Association, Chester I. Campbell, manager, 5 Park Square.
- Mar. 9-14.....—Buffalo, Convention Hall, Sixth Annual Automobile Show, Automobile Club of Buffalo. Dai H. Lewis, manager.
- Mar. 21-28.....—Toronto, Canada, St. Lawrence Arena, Automobile Show. R. M. Jaffray, manager.
- Apr. 5-12.....—Montreal, Canada, Arena, Third Annual Automobile and Sportsman's Show. R. M. Jaffray, Mgr.

#### Motor Boat Shows.

- Dec. 7-14.....—New York City, Grand Central Palace, National Association of Engine and Boat Manufacturers. Chester I. Campbell, manager, 5 Park Square, Boston.
- Jan. 1-8.....—Chicago, Coliseum, National Association of Engine and Boat Manufacturers. Chester I. Campbell, manager, 5 Park Square, Boston.
- Jan. 25-Feb. 1.—Boston, Mechanics' Building, National Association of Engine and Boat Manufacturers. Chester I. Campbell, manager, 5 Park Square, Boston.
- Feb. 3-8.....—Buffalo, Convention Hall, First Annual Power Boat and Sportsman's Show, auspices of Buffalo Launch Club. Dai H. Lewis, manager.
- Feb. 20-Mar. 7.—New York City, Madison Square Garden, Fourteenth Annual Motor Boat and Sportsman's Show.

#### Races, Hill-Climbs, Etc.

- Nov. 26-28.....—Chicago, Three-day 600-mile Reliability Race, Chicago Motor Club.

### FOREIGN.

#### Shows.

- Nov. 12-Dec. 1.—Paris, Exposition Decennale de l'Automobile, Grand Palais, Esplanade des Invalides, Automobile Club of France.
- Nov. 23-30.....—London, Agricultural Hall, Stanley Show.
- Dec. 5-22.....—Berlin, Germany, Automobile Show.
- Dec. 21-Jan. 2.—Brussels, Show, Palace of the Cinquantenaire.
- Jan. 18-Feb. 2, '08—Turin, Italy, Fifth International Automobile Exhibition, Palace of Fine Arts, Valentino Park, Automobile Club of Turin.
- Mar. 21-28.....—London, Agricultural Hall, Cordingley's Show.

#### Races, Hill-Climbs, Etc.

- Dec. 8.....—Paris, Straightaway Aeroplane Speed Test, auspices of "L'Auto."
- Dec. 8.....—Paris, Break-down Competition, auspices of "L'Auto."
- May, 1908.....—Paris, Competition for Agricultural Automobiles, auspices of "L'Auto." (Exact date to be announced.)
- May 12, 1908....—Sicily, Targa Florio, Automobile Club of Italy.
- June 20-July 5.—Grand Prix, Dieppe Circuit, Automobile Club of France. (Exact date to be announced.)
- August, 1908...—France, Coupe de la Presse, Automobile Club of France. (Exact date to be announced.)

## MAINE'S GROWING WORTH AS AN AUTO STATE

PORTLAND, ME., Nov. 11.—No better proof of the growth of the automobile industry in Maine can be obtained than that furnished by the Secretary of State at Augusta. Registration of automobiles is still going on, though it is about over for the season. The registration law went into effect in this State in 1905, and since that time 2,221 numbers have been issued to owners of cars in Maine. The totals for the three years in which the law has been in effect show that more machines have been registered this year than during any of the previous years. In 1905 the number of automobiles registered was 736, while in 1906 there were 649 registered, showing a falling off of 87 compared with the business of the preceding year. The number registered to date in 1907 is 836, showing a gain of an even hundred over the business of the first year. The number of automobiles registered during October was 41, the number of licenses issued to operators 48, with a total of 2,616, and the number of motorcycles registered 4, with a total of 228.

Automobile agents in Portland report that the past season was the most successful in the history of the industry in this State. Portland is the distributing point for Maine and the majority of the cars coming here have to pass through this city. The demand during the whole of the season has been great and conservative business men, the last whom one would think would take up the sport, have come forward and purchased high-priced cars.

During next season there will not be as many agencies in Portland, but those that will be here are well backed financially and form the backbone of the industry here. The Spear Auto Company has just been organized to handle the Ford cars. Albert M. Spear, Jr., is the manager of the concern. Mr. Spear is practically the pioneer in the business in Maine. He first handled automobiles for the F. B. Bailey Co. He was later identified with the Maine Motor Carriage Company for several years, and last year he was the manager for the J. A. Dowling agency. He has now branched out in business for himself and the indications point to a successful year.

The other agencies in Portland and the cars they will handle during 1908 as far as the stock has been selected are:

J. A. Dowling, Thomas; Maine Motor Carriage Company, Stevens-Duryea, Peerless, and Pope-Hartford; Stoughton & Folkins Company, Maxwell; Herbert A. Harford, White Steamer; Stranahan-Eldridge Company, Buick; F. A. Nickerson, Pierce Great Arrow; L. C. Gilson Company, Stanley and Reo; The Swan Company, Cadillac.

During the past season more visitors have come to the State of Maine than during any other year. Conservative estimates place the number of out-of-the-State callers at 2,500. Practically all of these have represented the richest men in the great cities who have been on their way to the Maine summer resorts of the State. The coming of fall saw little diminution in the numbers, hundreds coming to take advantage of the excellent hunting.

Though the third annual automobile and power boat show of Portland is still four months off, exhibitors are already being hard-pressed to secure space. The show will be held at the Portland Auditorium during the week beginning February 24 and will, as in past years, be under the direction of Frederick M. Prescott, of Boston. The exhibition for 1908 promises to be the biggest and best the city has yet had and the decorations for the event will be elaborate in the extreme.

### CHEMICAL AUTO ENGINE FOR BRIDGEPORT.

BRIDGEPORT, CONN., Nov. 18.—Within the next two weeks the big Locomobile chemical engine, built by the Locomobile Company for the city of Bridgeport, will be completed. The body was designed and built by the Bridgeport Vehicle Company and is ready for mounting on the chassis. The new chemical fire engine will make its trial trip through the streets of Bridgeport as soon as completed, and it is confidently anticipated that its success will bring about the adoption of other auto fire-fighting apparatus.

### PASSING OF THE HORSE ILLUSTRATED.

Ever since there has been such a thing as an automobile, the ultimate passing of the horse has been freely predicted, and the fulfillment of the prophecy, as illustrated by the sight of a horse towing a broken-down car home, has furnished abundant copy for the cartoonist. To turn the tables, the Studebaker Brothers Company recently adopted the novel expedient shown by the accompanying photograph. Three big Studebaker electric trucks were each loaded with a team of heavy truck horses and their usual burden pulled behind. In this manner, the novel cavalcade paraded the length of Broadway from Forty-eighth street to the Battery, and the procession, together with the moral it so pointedly illustrated, attracted no end of attention along the route. As a wind-up to the parade, the 3 1-2-ton trucks were delivered to the H. B. Clafin Company, which makes a total of six vehicles of this size and make now employed by the latter firm.

**Are Six-Cylinder Cars Striking Wide of the Mark?** Whatever may be the merits of the six-cylinder motor, as compared with the four, it is quite plain that merely tacking an extra pair of cylinders on the existing four-cylinder engine is not the most efficient means of taking advantage of these benefits. And this is exactly what the majority of builders of six-cylinder models for the coming season have done. Granted that the extra flexibility, smoothness of running, and capacity for taking grades with less gear-changing compensate for the extra mechanism involved, it can hardly be said that this forms a sufficient reason for making the six-cylinder car a ponderous creation that well merits the title of road locomotive. But this is what the average builder who is marketing a car of this type is making of it, in support of which it may be mentioned that the majority of the six-cylinder cars revealed at the shows in New York City averaged 70 to 90 horsepower. They were rated far more conservatively than this, of course, but nominal ratings do not alter the facts. The reason for this is equally plain, as most of the makers are still in more or less of a quandary regarding the six-cylinder car. They feel certain that there will be a demand for it, but do not wish to go to any unnecessary expense in placing themselves in a position to take advantage of this demand. If the six-cylinder type is the car of the future and is destined to eventually supplant the four, as so many believe, then some of the present developments along this line certainly seem designed to place that day further off, rather than to bring it nearer.

**A Vital Lesson from the European Situation.**

One thing which stands out unmistakably clear in the European shake-up—variously designated as crash, revolution, evolution, and dull season—is the disfavor into which the high-powered car has fallen. Enter any French or Italian factory producing both large and small models, ask for a \$7,000 60-horsepower car, and it will be produced on the spot. But state that your wants are a modest 16-20-horsepower chassis, and although you may offer spot cash you will be asked to wait a few weeks for delivery.

Most significant is the fact that instead of being a temporary glut due to overestimation of the possible number of users of automobiles, the slump is the outcome of the decision of the automobile public that there is little need for high-powered cars. From the early days when a single cylinder under a big bonnet developed eight horsepower users have been led on to twos, fours, and sixes, each season's car bigger and more powerful than its predecessor, until all natural requirements have been surpassed. The number of persons capable of purchasing powerful road locomotives has not decreased, but the number of those willing to face the maintenance expenses of a "sixty" when a "twenty" will meet all natural requirements is not as large as it used to be, as European constructors are finding out to their cost.

In this connection there is a significant story in the report of the Royal Automobile Club of Great Britain on the 15,000-mile journey of the Hotchkiss six-cylinder car. Tire expenses worked out at the rate of twelve cents a mile; gasoline consumption was not better than 7 1-2 miles to the gallon, tires and gasoline together approximating sixteen cents per mile. This does not substantiate the theory of advocates of six-cylinder cars that the smoother-running engine diminishes wear of tires, nor is any consolation to be found in the plea that the car is not one of the best of its class.

There will always be a certain demand for powerful engines for elaborate closed touring cars and for the special use of speed lovers, but America will find, as Europe has already discovered—and that at no distant date—that the popularity of the monster has gone. With the lesson before them, it is to be hoped that home constructors will be better prepared to meet this phase of evolution than their confrères on the other side of the Atlantic.

**Overwhelming Influence of Fashion on Auto Design.**

If there be any one thing of current production on which the influence of fashion would be regarded generally as a minus quantity, machinery would most naturally be accorded that distinction. It is nothing strange that fashion should dictate body lines, upholstery, or the details of finish, but that its influence is much more far-reaching than these purely non-technical matters must be evident to anyone who has observed the trend of design during the past few years. Three years ago there were a number of makers who had evolved systems embodying numerous special features of design, on which they dwelt at great length and to which were ascribed many, if not all, of the superior points offered by their productions. Observation brings to light the fact that many of these have gone by the board in the interim, so that the numerous distinctive features which formerly served to identify such cars have, in the 1908 models, been completely overshadowed by the demand for a machine that shall conform as closely as possible to the dictates of fashion.

Not that these particular details of design and construction were lacking in merit—probably the truth of the matter would show them to have been quite the contrary in some instances—but they had the fatal defect of not conforming to what the automobile buyer has come to consider as a standard. On the other hand, many of them were nothing more than talking points, and as such deserved to be eliminated, as the car was better without them. It is not to be presumed from this, however, that American cars, one and all, have settled down to a single standard, but the trend is a striking illustration of the influence of fashion on something generally considered beyond its pale.

## SUCCESSFUL OPENING OF THE BALTIMORE SHOW

BALTIMORE, Nov. 18.—Shortly after eight o'clock on Saturday night, Baltimore's third annual automobile show was opened to the public in the hall and warerooms adjoining the garage on Mt. Royal avenue, the scene of the first and most successful show ever held in Baltimore. Only about half the cars to be exhibited had arrived, and it was not until Sunday night that five carloads of exhibits arrived from the Philadelphia show, which were soon placed in shape by a gang of workmen.

Despite the absence of the chief exhibits from Philadelphia, the opening night was a successful one, and a large audience inspected the machines and the accessory departments. This year there have been many new features added to the show. Profuse decorations—bunting and flags—make an attractive setting for the big machines, while a concert is rendered each day and

evening by a concealed orchestra. One of the features of the show was the Winton and Maxwell exhibits, which arrived Sunday night. In the spaces to be occupied by the Philadelphia exhibits were large signs: "Wait for us until Monday night." The exhibit of the Maryland Motor Car Company, makers of the Maryland, the only car made outright in Baltimore, also attracted considerable attention. The machine is operated by an electric motor, and is made by the Sinclair-Scott Company.

While the auto show is holding the center of the stage, much interest was manifested in the private show of Tuesday and Wednesday at the Hotel Belvedere, where the Palmer & Singer Manufacturing Company exhibited their polished Matheson chassis that was the talk of the recent New York show. The agent in Maryland is the Matheson Automobile Company.

### SPACES FOR DETROIT DECEMBER SHOW.

DETROIT, MICH., Nov. 18.—The drawing for and allotment of space in the show which is to be held under the auspices of the Detroit Auto Dealers' Association, in the big pavilion at River-view (formerly Wolf's) Park, December 9-14, took place at the office of the association Thursday evening. The Cadillac Motor Car Company was the lucky one in getting first choice of space, J. P. Schneider and Grant Brothers, drawing second and third choices respectively. Strangely enough, the Ford Motor Company and Maxwell-Briscoe-McLeod Company drew 13 and 14 respectively. Inasmuch as I. A. McLeod is chairman of the Exhibition Committee, and Mr. Pelletier, advertising manager of the Ford Motor Company, is manager of the show, the luck of these two occasioned much amusement among the other applicants.

Henry Ford has promised to uncover at his home show, for the first time, the new Ford models about which there has been much speculation in trade circles. Winton will show no less than six models, including his six in various styles of body. There will be several Maxwell and Reo models, all the Pope vehicles, Whites, and other makes.

### SAN FRANCISCO NOT TO HOLD A SHOW.

SAN FRANCISCO, Nov. 10.—At a meeting of the San Francisco Automobile Dealers' Association, held last night, it was decided to abandon the proposed automobile show for the present season. Few of the dealers have been able to secure their new cars, and it was felt that an attempt to hold a show at this time would result in a poor and incomplete exhibition. The members of the association were unanimously of the opinion that it would be better to abandon the show for the season rather than postpone it indefinitely, as there was no certainty when it would be possible to secure sufficient cars to make a creditable showing. This course was adopted with but little discussion.

### PHILADELPHIA'S SHOW A BIG SUCCESS.

PHILADELPHIA, Nov. 18.—Opened a week before with not a few misgivings—due in large measure to the present tight-money time—the seventh annual automobile show of the Philadelphia Automobile Trades Association came to an end last Saturday evening in a blaze of glory and with an attendance that created a new record for a record-breaking week. Not only were all local attendance figures shattered—and this despite the inclusion of two double-price nights—but the total gate receipts exceeded the previous best by many precious simoleons; sales were more plentiful, and excellent "prospects" were booked in sufficient numbers to keep agents and branch managers on the go for many a week to come in the effort to convert them from possibilities to sure things. It was, indeed, a great show.

### PROVIDENCE SHOW IN FEBRUARY.

PROVIDENCE, R. I., Nov. 18.—Frank M. Prescott, who managed the previous automobile show in this city, will have charge of next year's event that is to be held from February 1 to 8 under the auspices of the Rhode Island National Guard. The new State Armory will be used, and as it has five times as much floor space as Infantry Hall, which housed the show last year, it is expected that all prior events of the kind will be totally eclipsed. It will be held in conjunction with a military carnival.

### NO REDUCED RATES TO CHICAGO SHOW.

F. C. Donald, commissioner of the Central Passenger Association, Chicago, has notified the American Automobile Association and the American Motor League that there will be no reductions in railroad fares to members of those organizations attending the Chicago show, November 30 to December 7. It is understood that abuse of the privilege by the American Motor League is responsible for the declination to grant rates.

## PROOF THAT AUTOMOBILE HAS COME TO STAY

FROM THE CLEVELAND PLAIN DEALER.

THE real moral to be drawn from the popularity of automobile exhibitions is the proof which it affords of the theory that the automobile has come to stay. It is not a fad, like the bicycle, roller skates and tiddle-de-winks. It is an accomplished fact. It is not the automobile but the horse that is on an unstable footing. The automobile, once the plaything of the very rich, is now utilized in numberless activities of life. It is a delivery van and an ambulance, a fire engine and an advertising dodge, a racer for the high spirited and a family hack horse for the elderly woman. Everywhere it is the "rubberneck car," and in some places it is the omnibus. It is fast losing its aristocracy,

fast becoming the most democratic of vehicles. The day is at hand when the man who drives a horse will be accused of plutocratic affectation.

Meanwhile may the automobile show live long and prosper. It has become a fixed annual affair in all cities where automobiles are commonly in use. For the automobile owner and prospective purchaser it provides an easy way for the comparison of the merits of the various makes. And for those who have no automobiles and who do not aspire to own one, the exhibitions furnish as pleasant an amusement as the horse shows, and are infinitely more instructive.

### HOW THE AUTO CROSSES AFRICA.

A hazardous trip equal in daring to the Pekin-Paris tour is now being undertaken by Lieutenant Colonel Grätz of the German Army. The undertaking is made to prove the practical utility of the automobile in colonies where no railways exist.

The route starts from Dar-es-salam on the east coast of Africa and traverses the "Dark Continent" to Sawakomund on the west coast, starting and ending in German territory, but passing through Rhodesia and Bechuanaland.

Leaving Dar-es-salam the route follows the old caravan road to Tabora, which is the largest city in German East Africa; then it turns south to Bismarckburg on Lake Tanganika. This last section is considered to be probably the most difficult stretch of the trip; especially the descent to the shores of Lake Tanganika. The route then continues through Rhodesia to Karonga at the north end of Lake Victoria-Nyassa, then on rafts to Domari Bay at the south end of the lake; next it crosses a mountain chain to Fort Jameson, and thence to Miwomboshi, where it intersects the Cape to Cairo Railroad. The road from here to Bulawayo, the capital of Mozambique, is reported fairly good. Beyond it is planned to reach Palapye and then down from the high plateau to Kalahari in a desert region. This part of the route is not considered so very difficult to trace owing to the fact that Professor Passarge and several English have covered it and prepared road directions and maps. At Rieffontain the route again enters German territory, and the rest of the way to the Atlantic coast is not deemed particularly difficult.

A Gaggenau car, made in Germany, is being used. It has been specially fitted with an enormous gasoline tank.

### CONCERNING THE ORMOND-DAYTONA MEET.

An arrangement has been consummated between the Florida East Coast Automobile Association and the Florida East Coast Railway interests in Florida, whereby the two will jointly conduct the annual race meet on the Ormond-Daytona beach. W. J. Morgan, who was responsible for the inauguration of the annual Florida meet, will be the general manager of the affair as usual. It had been anticipated that the Racing Board of the A. A. A. would be approached by the F. E. C. A. A. and asked to conduct the next meet on the Ormond-Daytona course. Apparently a majority of the Florida organization prefers that the meet be under its own direct control, though this action was taken by the F. E. C. A. A. previous to the conference of its representative, ex-President Asa Paine, with members of the A. A. A. Racing Board in New York City, and at a time when there was no certainty of anything being accomplished in this direction. The races will probably take place during the third week in March.

### COMMITTEE FOR STOCK CHASSIS RACE.

T. F. Moore, secretary of the promoting organization of the stock chassis road race, proposed to be held in Westchester county in April next, announces the executive board and rules committee just appointed by Robert Lee Morrell, the general chairman. The list is as follows: Col. George Pope, Hartford, Conn.; Henry Ford, Detroit, Mich.; E. R. Hollander, New York City; H. A. Lozier, Plattsburgh, N. Y.; A. Massena, New York City; C. A. Singer, New York City; James Joyce, Providence, R. I.; Paul Lacroix, New York City; Hayden Eames, Cleveland, O.; F. P. Brand, Williamsport, Pa.; Walter Allen, New York City, and F. B. Stearns, Cleveland, O. Mr. Morrell's intention is that this board, in addition to framing the rules, will decide upon the entry fee, date of the race, and take charge of the contest.

### A. A. U. BARS PROFESSIONAL AUTOMOBILISTS.

At the annual meeting of the Amateur Athletic Union of America, held at the Grand Union Hotel, New York City, November 18, it was decided to refuse amateur registration to all automobilists who have raced for cash, or who have competed in races with professionals.

### NOT RESPONSIBLE FOR DRIVER'S NEGLIGENCE.

PHILADELPHIA, Nov. 18.—The familiar rule of law under which the master is not responsible for injuries accruing from a servant's negligence when not engaged in the business of his employer, has been applied to the case of a chauffeur who runs down a person and kills him, while using the car unknown to the owner, by the State Superior Court of Pennsylvania, reversing a decision of the Court of Common Pleas in Philadelphia. The case was decided on the appeal of an owner whose car killed a child while being driven by his servant who had taken several of his friends riding in opposition to the wishes of his employer.

### FEDERAL JURISDICTION ON CONDUIT ROAD.

ROCKVILLE, MD., Nov. 18.—In the case of J. A. Lutz, who was fined by the Glen Echo authorities for fast driving on the Conduit Road, an appeal to the higher court has just been decided by Judge Henderson, who declares that the jurisdiction of the United States over the Conduit extends to its use as a road, and that the automobile regulations of the town of Glen Echo or of Montgomery County, Maryland, are consequently of no force and effect on it. He added that the State has general jurisdiction over the road, but that it is not a public highway within the meaning of the statute.

### STRANG'S SOUTHERN BARN STORMING.

Walter Christie's front-drive racer is somewhere in the South, its performances being contrary to the wishes of the owner and apparently of a somewhat unsatisfactory sort. Strang, apparently under the management of one W. H. Pickens and calling himself Louis Christie Strang, is driving the champion mile car in unsanctioned race meets, and of course it means his future disbarment from sanctioned events. From the Birmingham (Ala.) *News* comes the following "story" of a recent "meet" there:

"The automobile races at the fair grounds Tuesday afternoon proved to be a flat failure for the reason that Strang's car blew up when he had gone half a mile and because of the lack of interest in the three or four local events. A remarkable thing about the accident was the fact that the driver, Louis Christie Strang, was not hurt, as the timers claim he was going a mile in less than a minute when there was a loud report, a puff of smoke and the car came to a standstill at the half mile post. It was announced that the crank-tank burst, causing the cylinder head to blow out. The reason given for the bursting was that 94 per cent. pure gasoline was being used when 84 per cent. would have been safer.

"There was little interest in the other events on the program and few people were in the grandstand when they were over. The local owners themselves realized that enthusiasm died when the crank-tank burst and the mile event was declared off until some future time when it is said Strang will once more make a dash around what has been declared as 'the fastest mile track in the world.'"

### GEARLESS GREYHOUND, 75 H.P., \$4,000.

Sometimes, in even the best regulated print shops, the types get mixed, and this was the case in the November 14 advertisement of the Gearless Transmission Company, 295 Plymouth avenue, Rochester, N. Y., which concern manufactures three models as follows: "Model Seventy-five, of 75 h.p., selling at \$4,000; "Model Sixty," of 60 h.p., selling at \$3,500; and the "Greyhound," of 75 h.p., selling at \$4,000. The advertisement erroneously stated that the latter car sold for a thousand dollars less.

In the report of the very successful experiments conducted by the New York School of Automobile Engineers with alcohol, it was erroneously stated in the last issue of *THE AUTOMOBILE* that the fuel employed consisted of alcohol with 10 per cent. of benzene and 2 per cent. of wood alcohol. The U. S. Industrial Alcohol Company, who supplied the fuel, inform us that it is composed of 90 per cent. of 188 degree proof grain alcohol, 10 per cent. of wood alcohol and 1-2 per cent. of benzol.

**HOL-TAN COMPANY TO MARKET AMERICAN CAR.**

Since relinquishing the Fiat agency, developments in the metropolitan representation of American cars have been looked for on the part of the Hol-Tan Company, of which C. H. Tangeman is president and Harry Fosdick, vice-president, and the announcement that this concern had just concluded negotiations for the building of a special American car to be marketed under the name of Hol-Tan is of considerable interest. The new car is to be built by the Moon Motor Car Company, St. Louis, Mo., of which L. P. Mooers, originally with the Peerless Company, is the designer. It is intended to follow foreign practice to a certain extent in marketing the cars, the bodies being supplied by Locke, Quinby and

HOL-TAN STANDARD MODEL WITH THREE-PASSENGER BODY.

Demarest, in many cases, to the purchaser's order. Two models will be offered at first, the smaller of which will be known as the Hol-Tan Standard, while the larger car is the Hol-Tan Special, the chief points of difference being in the length of the wheelbase, size of the wheels and chassis length. Both will be equipped with the Moon 4 1-2 by 4 1-2-inch, four-cylinder water-cooled motor, fitted with dual ignition employing the Eisemann high-tension magneto and a standard coil and accumulator system. The car will be known as a 25-horsepower model, though even the conservative A. L. A. M. rating gives it 32 horsepower. The gear-set provides four speeds forward and operates on the selective plan, final drive being by shaft. With a touring body and full equipment, the weight of the Standard model with its 110-inch wheelbase, is 2,500 pounds, and it is listed at \$3,000. It will also be fitted as a two, three or four-passenger roadster, but no bodies will be built to order for this chassis. The Special type has a 121-inch wheelbase, permitting the use of a five-passenger tonneau, or of the fitting of a limousine or landaulet type of body. Chassis only lists at \$2,750, and at \$3,750 with touring body.

**ONE MAN'S OPINION ON MAGNETO IGNITION.**

Designer Sam Hartley, of the Cleveland Motor Car Company, sets forth the merits of magneto ignition as follows:

"We believe that the gasoline car should be independent of outside necessities so far as possible and that, given fuel and oil, there should not be a further expense to the user, but that by the mechanical generation of electricity the ignition problem should be made reliable, durable and without further expense to the buyer for batteries or for charging storage cells, which may be exhausted at inopportune times, as well as being some considerable expense to replace or recharge. Further than this, the magneto gives a better spark than the usual battery, because it is not considered advisable to carry a sufficient weight of battery to produce a spark larger than actually necessary, although it is well recognized that an increased spark size results in increased power and therefore is really economical in the saving of fuel. This as well affords greater satisfaction in the vehicle, as greater flexibility arises from the increased motor power given by the large spark.

"We prefer the gear-driven magneto, because this produces the electric impulse just when wanted and therefore of greater size than the direct current, friction-driven magnetos frequently used, although these latter are quite satisfactory. As an adjunct and a reserve against any possibility of trouble, we provide a set of batteries, but since these are seldom used, we avoid the expense connected with them. The rapid growth of the use of the magneto is evidence of this great value and is simply another pointer that automobile makers are sparing no expense to give their users the most reliable and economical constructions possible to build."

**RUNABOUTS NOW A BUSINESS NECESSITY.**

INDIANAPOLIS, IND., Nov. 12.—There will be a large number of changes in Indiana automobile agencies next season. Probably the most important change will be in the State agency of the Marmon, which has been held for the last two seasons by the Gibson Automobile Company. This will be held in 1908 by the H. T. Hearsy Vehicle Company, who have added the Marion in addition to their old agencies, consisting of the White, Rambler, and Pope-Waverly.

There are a number of companies seeking representatives in the city that have not been represented in the past. It is believed that the auto buggy manufacturers, which are without representatives in the city, with one exception, will make a strong effort to get business here next year.

The 1907 season has been much larger than that of last year. More and higher priced cars have been sold. There has been a great demand for runabouts, chiefly among physicians and city and traveling salesmen. Men buying automobiles for pleasure have, with few exceptions, purchased three-passenger roadsters or touring cars.

It is safe to estimate that from 1,300 to 1,500 automobiles have been sold in Indianapolis this season. Indications for next year are good, and many orders for March, April and May delivery are already filed. Preference has been shown to a large extent for six-cylinder cars and the popular roadsters for next year. However, there is no fear but that four-cylinder touring cars and the runabouts will retain their popularity.

"Runabouts," said a prominent local dealer, "are like the bicycle. They have grown from a pleasure vehicle to a business necessity and now constitute something that many business men in certain lines find that they cannot well afford to do without."

**FIRE IN LEATHER TIRE GOODS CO.'S PLANT.**

BOSTON, Nov. 18.—Fire which started in the plant of the Leather Tire Goods Company at Newton Upper Falls, a suburb of this city, on Thursday last, did a limited amount of damage. The concern manufactures the patent Woodworth detachable steel-studded leather treads for protecting pneumatic tires. No serious interruption to business was caused.

E. J. MOON IN CAR OF THE SAME NAME.

NORTH SIDE GARAGE, CHICAGO'S NEWEST ARTISTIC TYPE.

#### Latest Addition to Chicago's Garage List.

CHICAGO, Nov. 18.—Among the influences that are tending to improve Chicago architecturally, not the least important is that of the new garages which are being erected in all parts of the city. A representative instance of this is to be found in the establishment of Joseph Paupa, Jr., known as the North Side Garage, and which is located at 605-607 North Clark street. Some idea of the pleasing facade of the building may be obtained from the accompanying photograph. The building is of fireproof construction, and the garage space, which measures 50 by 155 feet, is entirely clear of supporting pillars. The remainder of the building is devoted to an accessory supply store, measuring 20 by 50 feet, a chauffeurs' reading room and a waiting room. The building is electrically lighted and steam heated, and includes in its facilities a charging plant capable of taking care of twelve electric cars at once. This is as finely equipped a garage as is to be found anywhere in Chicago.

#### New York State's Garage List Growing Fast.

AUBURN, N. Y., Nov. 18.—A notable addition to the list of up-to-date New York garages was made with the opening of the establishment of the Auburn Automobile Company this summer. This concern, of which George H. Leonard is the proprietor and manager, has had an 80 by 60 one-story building especially erected for the purpose. It is of brick and concrete construction and is fitted with offices and salesroom, chauffeurs' locker room and ladies' waiting room at one end and a complete repair shop at the other. One corner is devoted to charging and caring for electric and storage batteries. This year the Auburn Automobile Company has handled the Franklin, Buick and the Pope-Waverley electrics and has done an excellent business with all three.

#### Model Garage Opened in Bridgeport.

BRIDGEPORT, CONN., Nov. 18.—The New York to Boston route is becoming famous for its garages and a notable addition to the chain is to be found in the recently opened Blue Ribbon garage on Fairfield avenue, Bridgeport. The building is three stories in height and is of steel and concrete from cellar to roof, even the latter being of concrete. In fact, there is a testing station for cars on top of it. The freight elevator runs the height of the building, accommodating the largest cars, and is to be extended to the roof. Among the conveniences are a ladies' waiting room, chauffeurs' room and every facility for handling cars.

#### NEW DOINGS AMONG THE GARAGES.

Spencerville, O.—H. A. Mack, the pioneer auto dealer in this section, has had erected for him a modern garage building, on the site of his former establishment, on East Market

street. It is two stories high and measures 50x100 feet; of fireproof construction throughout, and is equipped with every facility for handling and repairing cars.

Omaha, Neb.—The Powell Automobile Company has gone out of the garage business and will in future devote its entire attention to the handling of a general line of accessories and supplies. The company's location will be at 2010 Farnam street. Several men will be put on the road this fall, and a much larger territory covered than previously.

San Mateo, Cal.—Before the end of the year the garage facilities of this town will have two notable additions in the shape of the new garage of Brown Brothers, at B street and Fourth avenue, now in operation, and the \$25,000 garage building of the Pope estate, being erected at Third avenue and El Camino Real, which is expected to be finished in December.

Madison, Wis.—The model establishment on which the Hokanson Automobile Company began construction last summer is now about completed. It is located nearly opposite the old place, on East Doty street, and consists of a one-story and basement structure measuring 77x132 feet. It is of brick construction, with very few posts on the floor, and has been erected at a cost of \$10,000.

Savannah, Ga.—Thompson & Company, who carried on a general business, with salesrooms at Bull and Jones streets, have been succeeded by the Wilson Automobile Company, which has established quarters at 349 Bull street, where they have fitted up a place to take care of repairing and storing as well as selling cars. Renting will also be a feature of the business. Thompson & Company became bankrupt, and the Wilson Automobile Company is nominally its successor.

Charleston, S. C.—This city can boast of one of the largest automobile livery services in the entire South. It is known as the Charleston Hotel and Auto Livery Company, and during the past summer has moved into a new and commodious garage just opposite the hotel on Haynes street. It is a four-story brick building, the interior of which has been remodeled especially for this purpose. The company now has in operation three transfer 'buses, a sight-seeing car of large capacity and eight touring cars for rental purposes, the different cars being Mitchells, Ramblers and Reos.

Detroit.—Under the title of the Joseph Chene Auto Garage Company, Detroit acquired a notable addition to its already long list of automobile dealers, and the new firm has had erected for it a building quite in keeping with its importance in the trade. It is located at 1086-1090 Jefferson avenue, and is one of the most completely equipped in Detroit. The firm consists of Joseph Chene, an expert machinist, who has been with the Olds, Cadillac, Northern and Standard Automobile companies, and Bert Allen, an associate of Mr. Chene's in the repair department of the Standard Company. It will be evident from this that the new firm will make a specialty of repairing.

INTERIOR OF THE GARAGE OF THE AUBURN AUTOMOBILE CO. ]

**T**HERE is less actual business in automobile shows for accessory people than for car makers, yet the parts and supply men feel obliged to go into every show. Concerning this, H. T. Dunn, president of the Fisk Rubber Company, says: "It would be a waste of time for the tiremakers to go to a show seeking wholesale business. We have an organization for that trade. As to retail business, tires are not an accessory that a man buys and orders sent home, as a rule. About all we can hope to do is some advertising and missionary work. In our own case this is eminently satisfactory. The presence of all the different grades of tires at the shows gives men who really want to know a chance to make comparisons which otherwise are difficult, and this is the best thing for any exclusive class of goods such as Fisk tires. Going from one stand to another nearby, it is possible for a man to learn what there is about tires that warrants the Fisk being a little higher in price. A field for educational work is chiefly what the shows offer the makers of tires.

With the increase in Lozier agencies, due to the campaign which the Lozier Company is making for wholesale business, the territory has been separated into two divisions, eastern and western, the former in charge of W. S. M. Mead, and the latter under the direction of F. C. Chandler. The retail sales department of the metropolitan district will be in charge of C. A. Emise. Mr. Chandler, for a number of years manager of the Hamburg branch of the Lozier Company, will also have charge of the foreign sales department, and as this firm has previously done a large export business in bicycles and marine motors, this places them in an excellent position to enter the foreign market with their cars.

Interest in the taxicab development in New York is revealed by the recent incorporation of two companies to undertake this business. One is the National Taxicab Company, organized by W. Bernard Vanse, Brooklyn; George A. Knoblich, New York, and Woodford Mobry, New York, with a capital of \$25,000, while the other is the Manhattan Taximeter Company, having a capital of \$5,000, of which Cecil P. and Arthur A. Stewart, and Arthur Kleve, all of New York, are the incorporators.

One million two hundred and fifty thousand tires is the total output to date of the great French house of Michelin. This is sufficient to equip 300,000 cars or a greater number than the total registration of automobiles in this country. Last year Michelin

did a \$11,000,000 business, including that of his English and Italian factories. Now that the big Michelin plant at Milltown, N. J., is in full operation, the output and consumption of these tires will be materially increased.

This item is from the Mobile, Ala., *Herald*: "There is a noticeable increase in the size of the automobiles to be seen on the streets in the city within the last few months. A year ago a large touring car was the exception, whereas now there are any number of goodly sized machines to be seen daily on the streets. One of the most recently purchased machines in the city is the largest ever owned by a Mobilian."

#### RECENT BUSINESS CHANGES.

The Frederick E. Randall Company, Boston, Mass., representing the Pullman and Pennsylvania interests in that city, have been reorganized owing to the death of the late Frederick E. Randall. Milber Dykeman is now president, Mrs. N. C. Randall, treasurer, and H. F. Cross, secretary. Charles Bates continues as general manager—in fact, the only new officer of the company is Mr. Dykeman.

The Oldsmobile Company of Canada has just moved into its new offices and sales-rooms, located at 80 King street, East, Toronto, Ont. An up-to-date garage and completely equipped repair shop having all modern facilities is conducted for the convenience of Oldsmobile owners in that section of the Dominion.

#### NEW AGENCIES ESTABLISHED.

The Studebaker Brothers Company has just opened a branch in Philadelphia, where a complete line of their gasoline and electric pleasure vehicles and trucks will be handled. The new branch will be in charge of A. J. King as manager and Frank Yerger as assistant. Mr. King was formerly connected with the Keystone Automobile Company, while Mr. Yerger was with Titman, Leeds & Company, the former Studebaker agents. The location of the new branch headquarters will be announced in the near future.

The John N. Loeser Manufacturing Company will continue to push the cars of the Logan Construction Company, Chillicothe, O., in the New York metropolitan district during the coming year. They have added a complete line of the Logan commercial vehicles for demonstrating purposes and

expect to do a largely increased business with this end during 1908.

The Pope agencies in Chicago have just been divided, Orlando F. Weber retaining the representation of the Pope-Toledo, while George F. Kehew takes the Pope-Hartford interests in that territory. Mr. Kehew started with the Columbia people at Hartford some time ago, but has handled the Moon and Queen cars in the interim.

The Glide interests for the South during the coming year have been taken over by J. S. Russell, who has taken the agency for the Southern States. Headquarters have been fitted up at 327 Baronne street, New Orleans, La., from which point agents will be appointed.

#### IMPERIAL IN PHILADELPHIA.

PHILADELPHIA, Nov. 18.—Show week as usual furnished its usual quota of trade sensations along "Gasoline Row." One of the most startling was the announcement that the Bergdoll Bros. have secured the local selling rights for the Imperial line. Just now the Bergdolls are rushing work on their big establishment at Broad and Wood streets, where they hope to install their full line—they will also handle the Welch and Benz cars—by the first of the year. Meantime they are carrying on business at 310 North Broad street. Joseph L. Keir, local Renault agent, has been secured as manager.

#### PERSONAL TRADE MENTION.

E. C. Morse, who has been connected with the sales department of the National Cash Register Company, Dayton, O., for the past eight years, has been appointed to the new office of "commercial manager" of the E. R. Thomas Motor Company, Buffalo, N. Y. He will have full charge of all matters pertaining to the advertising and sale of the Thomas cars, his past experience in what is generally conceded to be one of the world's best schools for salesmen fitting him well for his new position.

W. M. Botto, general sales agent for the Matheson Motor Car Company, is making the rounds of the local shows and exhibiting the 1908 chassis at the principal hotels. In Baltimore he is making his headquarters at the Belvedere; in Washington he will show at the New Willard; in Pittsburgh at the Schenley, and in Cincinnati at the Sinton. After the shows he will take the chassis to New Mexico.

E. P. Nussbaum, for many years general manager of the National Electric Supply

Company, Washington, D. C., and who, in the past few years, has been handling the well-known Harris oils, has just severed this connection with the Harris Oil Company to become a special sales representative of the Jones Speedometer Company, Broadway and Seventy-sixth street, New York City.

C. S. Henshaw, of the Henshaw Motor Car Company, 97 Massachusetts avenue, Boston, Mass., who handle the Oldsmobile and Columbus electrics in that territory, has announced that he will sever his connections with the firm in the near future and is open for negotiations with any large concern, New England territory with Boston headquarters being preferred.

Rene Beauchemin, formerly with the Lozier Motor Company, has again taken up the sale of Lozier cars, but for H. C. & C. D. Castle, Inc., who handle this line in the New England territory. He will make his headquarters at Boston.

H. H. Everett, a well known writer on automobile topics, connected in the past with *Outing*, *Collier's*, *Motor* and the *Cosmopolitan Magazine*, is now associated with A. B. Tucker in his well-conducted bureau of automobile publicity.

Burton Parker, formerly of the Hartford Rubber Works Company and later with the Fisk Rubber Company, has joined the Michelin Tire Company and will be located at the general offices in Milltown, N. J.

Frank E. Clark, formerly of the Western Tool Works, Galesburg, Ill., has been appointed purchasing agent for the American Motor Car Company, Indianapolis, Ind.

#### THE BANKRUPTCY LIST.

CHARLOTTE, MICH., Nov. 18.—A voluntary petition in bankruptcy has been filed in the United States Circuit Court at Grand Rapids by the Dolson Automobile Company of this city. Three Chicago creditors with claims aggregating \$1,000 are responsible for the filing of the petition. The book value of the assets reaches \$250,000, with unsecured claims of \$140,000. C. R. Hathaway of the Muncie Auto Parts Company, Muncie, Ind., has been appointed custodian of the plant, pending the naming of a trustee.

NEW YORK, Nov. 20.—John Gruenberg has been appointed receiver for the Duplex Ignition Company, manufacturers of spark-plugs and auto supplies, 307 West Thirty-sixth street, a petition in bankruptcy having been filed by Fritz Lowenstein, with a claim of \$1,075; W. T. Hoofnagle, \$259, and the Telephone Manufacturing Company, \$250.

NEW YORK, Nov. 20.—A petition in bankruptcy has been filed against the Kalb & Berger Manufacturing Company, 530 East Seventy-second street, maker of transmission gears, and other specialties, by the following creditors: D. S. Holcomb, \$700; Eaton, Schleich & Wall, \$49, and W. F. Dunker, \$425. Charles Weiser was appointed receiver.

#### FRANKLIN CO.'S SELLING PLAN.

Important changes in the selling organization of the H. H. Franklin Mfg. Co. have just been announced from Syracuse. The entire selling division which heretofore has been under the supervision of Mr. Franklin himself has been turned over to V. E. Minich, who has just been appointed assistant to the president.

Mr. Minich was formerly general manager of the Haynes Automobile Company of Kokomo, Ind. More recently he has occupied the position as advertising manager for the National Cash Register Company of Dayton, O. As director of the selling division of the Franklin Company, Mr. Minich will have under him the sales, sundry, and advertising departments, and the branches of the Franklin Automobile Company. F. R. Bump will continue as sales manager and J. G. Barker as manager of the sundry department.

Charles M. Steele, a former Chicago newspaper man, has been appointed advertising manager. Mr. Steele was until recently at the head of the publicity department of the National Cash Register Company, of Dayton, O.

The three branches of the Franklin Automobile Company at New York, Boston and Chicago are in charge of W. S. Jewell, C. E. Wheeler and F. L. Thomas, respectively. Frank G. Carrie, formerly New York representative for the Haynes Co., has been appointed assistant manager of the Franklin Automobile Company's branch in New York.

#### NEW TRADE PUBLICATIONS.

Soberly printed in black and gray, embellished only by a colored frontispiece, the Packard 1908 catalogue has a very distinctive appearance. Line drawings only illustrate the mechanical features of the 1908 output of the Detroit concern, and the word story does not err on the score of verbosity; it is sufficiently lengthy, however, to adequately cover all the distinctive features of Packard construction and to make known the improvements in detail over the model of the previous year.

In a business-like manner the Hatfield buggyabout for 1908 is presented to the public in a well-produced sixteen-page catalogue. The vehicle is driven by a double opposed air-cooled engine and has a number of features above the usual run of buggyabouts, all of which are clearly set forth in the publication. Its makers are the Hatfield Motor Vehicle Company, Miamisburg, O.

A very clear understanding of the structural features of the Holley carburetor can be obtained by a perusal of a booklet issued by the Holley Brothers Company, of Detroit, Mich. Sectional drawings and very explicit text matter make possible an appreciation of the features of the Holley in a manner which will be appreciated by the professional and the amateur.

The Kiblinger, an automobile haling from Auburn, Ind., where it is manufactured by the W. H. Kiblinger Company, has its virtues extolled in a catalogue just sent broadcast from headquarters. A romance is wovcn around the Kiblinger for those interested in romantic stories, and there are plenty of illustrations and descriptions for the technically inclined.

Details of the 1908 Mason automobile, built by the Mason Motor Car Company, Des Moines, Ia., are contained in the firm's new illustrated catalogue. The machine is a two-cylinder horizontal opposed, with single chain drive. Its features are well presented in the catalogue.

Frontenac touring cars and runabouts are presented to the public in an illustrated booklet of pleasing appearance, issued by the Abendroth & Root Manufacturing Company, of Newburg-on-the-Hudson, N. Y.

#### INFORMATION FOR AUTO USERS.

**The Hans Gasoline Gauge.**—It goes without saying that if every car were equipped with a gasoline gauge on the dash, there would be less need for an emergency fuel tank and fewer instances of being caught on the road with an empty tank. The Edmund E. Hans Company, Minneapolis, Minn., has brought out a gauge for this purpose, which consists of a float chamber of rectangular section, of approximately the same height as the depth of the gasoline tank and which is surmounted by an indicating pointer and dial, somewhat similar to a steam gauge in appearance. The indicating mechanism is composed of two pinions and a drum and is connected with the float by means of a cable of special braided silk, which is entirely unaffected by the action of gasoline and will last indefinitely. The apparatus can be used with any style of tank and whether operated by gravity or pressure, an important feature being

HANS GASOLINE GAUGE.

the fact that the indicating needle is not affected by the jolting or vibration of the car. The construction is of the simplest and all the parts are very substantial, so that the makers give an unconditional guarantee with the instrument. It can be used to equal advantage whether the tank happens to be hung under the frame at the rear, is placed under the seat or under the bonnet, and is made in special form for use on steam cars. The necessary connections are simple and easily made.

**Motor and Parts Specialists.**—The Michigan Automobile Company, Ltd., Kalamazoo, Mich., having discontinued the building of complete cars, is devoting its entire attention to the manufacture of motors, gear-sets and other machined parts in large quantities, being engaged at present in turning out one order for gear-sets which aggregates \$50,000. This concern manufactures all types of motors from one to six-cylinders and all styles of gear-sets from blue-prints, being specially equipped to produce this class of work in large quantities for prompt delivery. It is also in a position to do other machine work connected with automobile manufacture, such as cylinder-grinding, and is now installing a number of modern machine tools of the best types, which will make its facilities unequalled for the production of work of this special character. The members of the firm have had five years' experience in this particular line, following upon a number of years in other lines of machine shop practice.

**New Remy Magneto.**—As an entirely new comer for their 1908 line, the Remy Electric Company, Anderson, Ind., have brought out a high-tension magneto. This is styled the Type F, and is claimed to be the most simple jump-spark ignition equipment ever devised for a four-cylinder engine. No independent coil is employed and the magneto can be installed on a car with a minimum of expense. It is also adapt-

REMY TYPE F MAGNETO.

ed for use with single and twin-cylinder engines, the complete wiring in any case consisting of but a single connection between each spark-plug and the magneto, with a primary wire to the switch for shutting off the generator when stopping. This new magneto is of the true high-tension type, in that it has both the primary and secondary windings placed directly on the armature, but unlike most others, it employs no gearing or distributor. It is intended to run at the same speed as the motor crankshaft, and as the armature moves from a position with its core parallel with the fields, the primary circuit is mechanically broken and a high-tension current induced in the secondary winding of the armature, this being conducted through brushes and a simple arrangement of segments on a hard-rubber drum to the cables leading to the plugs. The point at which the primary circuit is broken may be advanced or retarded to an extent equivalent to 30 degrees on the circle of armature rotation, which gives ample leeway for altering the timing of the spark. The construction throughout is of the most durable nature and the magneto is both dust and waterproof, the only attention required being an occasional oiling. Some idea of the extreme simplicity of the new Remy may be obtained from the illustration.

**Improved Barrett Auto Jacks.**—For the season of 1908 "The Jack That Duff Builds," otherwise known as the Barrett jack, and made by the Barrett Manufactur-

IMPROVED BARRETT JACK.

ing Company, Pittsburg, Pa., has been improved by the addition of a new reversing lever which controls the movement of the jack, up or down. Working at the

front of the jack and displacing the side eccentric or thumbscrew formerly used, the reversing lever is always accessible, no matter in what position the jack may be placed under the car. And it is in ready reach without groping between the spokes of the wheel or crawling beneath the car. It is not even necessary to reach under the car to operate the lever, as a slight blow with the jack handle will set it as desired in a second. This ingenious device adds greatly to the efficiency and convenience of the Barrett jack, on which it is an exclusive feature, patents covering it now being pending.

**National Carbureter.**—Under the title of the "National," the National Auto Accessory Company, 84 State street, Boston, Mass., are just placing on the market a new carbureter which is claimed to embody numerous features of merit, and on which patents have been applied for. It is adapted to run with alcohol as well as with gasoline and one of its chief features of distinction consists of a non-seating air-valve that not only makes it noiseless, but sprays the incoming air around the gas-

NATIONAL SILENT VALVE CARBURETER.

oline nozzle in such a manner as to thoroughly mix it with the gasoline, completely vaporizing the latter. Its makers claim this construction makes it particularly adaptable to two-cycle motors of the three-port type, though it is equally well adapted to both two and four-cycle motors, and is intended for both automobile and motor-boat service. It is constructed of brass throughout with the exception of the float, and is made in standard pipe sizes.

**The Phelps Vehicle Recorder.**—This is a device which automatically records the movements of all kinds of vehicles, and has been constructed to meet the requirements of team and vehicle owners and operators, livery stables, cab companies, automobiles, motor trucks and the like. The entire apparatus is enclosed in a locked aluminum case, its record, which covers seven consecutive days, being made on sensitized dials, but the instrument differs radically from all other devices of this character, in that it requires no connection with the wheels or other moving part of the vehicle, and may be mounted in any convenient location in the body or top of the vehicle away from contact with passengers or merchandise. Moreover, it is unbeatable, as it cannot be opened without leaving a

record of that fact on the dial. The latter is printed on a hard surface paper with blue sensitizing, upon which a white record is made of an entire week, day and night. The clock movements used are twelve-day, nine-jeweled Seth Thomas, with compensating balance, and are not only accurate timekeepers, but are constructed to withstand the hardest kind of service without

PHELPS VEHICLE RECORDER.

derangement. It shows the number of stops, the time of starting, elapsed time of every stop and elapsed time between each start and stop, as well as time of night or day that the vehicle was in operation beside the time of return to garage and a complete record of movement during the night, if any, thus putting an effective stop on "joy riding." The entire mechanism is under lock and key and cannot be tampered with without detection, nor in any other way put out of service. The instruments are sold outright with a year's supply of dials and are handled exclusively by William S. Jones, 112 North Broad street, Philadelphia, or 101 West Sixty-sixth street, New York City.

**Grinnell "Rist-Fit" Gloves.**—Comfortable gloves are essential for the driver's peace of mind, and just what constitutes comfort in this respect has been made a study by the makers of the Grinnell "Rist-Fit" gloves, Morrison, MacIntosh & Company, Grinnell, Ia. As their name indi-

GRINNELL "RIST-FIT" GLOVE.

cates, these gloves fit snugly about the wrist, which is accomplished by providing a strap at that point, a slight pull on which draws the glove closely about the wrist, holding them neatly and securely in place, with the cuffs well up, thus keeping out snow and cold winds. The gloves themselves are made of soft, pliable "reindeer" and colt-skin leathers, which are claimed to possess exceptional wearing qualities and are not injured by either heat or wetting.

# AUTOMOBILE

VOL. XVII

NEW YORK—THURSDAY, NOVEMBER 28, 1907—CHICAGO

No. 22

CHICAGO, Nov. 28.—Holding a show under the auspices of an organization which includes the adjective national in its title does not necessarily imbue the event itself with that characteristic, but, for the past three years, the Chicago Show has had other and much more substantial claims to the honor than the mere fact that the National Association of Automobile Manufacturers was responsible for it.

Constituting, as it does, the only show of the year in which American makers come together regardless of trade or other affiliations, it has a claim on the title of national that is indisputable, and the event which will occupy every available foot of space in the Coliseum and First Regiment Armory, as well as the overflow of the commercial section in the Seventh Regiment Armory, during the period of November 30-December 7, will be more truly representative of the American industry as a whole than any other gathering of manufacturers that has ever been held in this country.

There will come together under one roof, figuratively speaking, makers of every class of power-driven vehicles that may be termed automobiles, from the smallest and most recent comers in the shape of buggabouts up to the most ambitious production of the old-established maker, the value of whose exhibit alone is frequently more than a score of smaller cars.

The fact that the aggregation thus assembled embraces not only all the most representative makers, but likewise the great majority of those generally referred to as "the American industry," will be evident from the fact that the bulk of the exhibitors is made up of the membership of the National Association of Automobile Manufacturers, Inc., the Association of Licensed Automobile Manufacturers, and the American Motor Car Manufacturers' Association, where complete vehicles are concerned, and the members of the Motor and Accessory Manufacturers, Inc., in the realm of those productions of smaller size, but equally great importance, that always serve to fill every

available inch of space not adapted to showing cars, and that add much of interest to every automobile show.

To the seasoned show-goer, the collection on the main floor of the Coliseum alone has a real national flavor, for here are invariably gathered that coterie of old-line makers who have always formed the backbone of the industry, and who are given the preference in the allotment of spaces to which their standing entitles them. And, in fact, age and responsibility of standing are the only qualifications that result to the advantage of the exhibitor in this manner, for otherwise the distribution of space is entirely according to lot, the drawing being held last July, when practically everything available was contracted for. This concentration enables the visiting dealer to examine practically all the productions of the year in one show, and, as usual, complimentary admissions will be issued to the trade during the usual hours and under the same conditions as before.

In the matter of decorations the Chicago show has always been distinctive, and, on the present occasion, Manager Miles has outdone all his previous efforts in this line and prepared a setting that will be a surprise to the seasoned rounder, as well as the newcomer who gets his first look at the interior of the Coliseum next Saturday afternoon and evening, for, unlike the New York shows, Chicago opens its doors in the afternoon.

Some idea of the magnitude of the task of decorating such a place may be gained from the fact that there will be approximately 9,000 square feet of oil paintings alone. There are 142 of these in all, ranging in size from 4x8 to 8x24 feet. The subjects of these paintings have not been selected at random, but, in the majority of cases, the smaller ones situated close to the exhibits represent scenes in which the cars shown near them

have actually taken part, while others picture American cars in all parts of the world, each scene representing an actual occurrence reproduced from a photograph. Racing has not been overlooked, the subjects including two scenes at the Vanderbilt Cup

**SAMUEL A. MILES,**  
General Manager N. A. A. M.

race of 1906, a race on the Detroit track, scenes at Brookland's track in England and the twenty-four-hour races at Morris Park. In other ways, the plan of decoration and equipment is even more elaborate than that of the last show, which was generally conceded to be the finest thing of the kind ever seen in connection with a purely industrial exhibition. The amount of material employed to complete this truly elaborate setting for the automobile is literally stupendous, and all of it has been designed to harmonize in a complete *ensemble*,

in which the automobile itself shall be the chief attraction and not the decoration. In other words, effort has been directed toward the creation of an automobile atmosphere, and that Manager Miles has more than succeeded in realizing this ideal goes without saying.

The great demand for space, which the amount available in both the Coliseum and the First Regiment Armory falls far short of filling, has led to the adoption of one expedient after another to extend the cramped interior of what appeared to be a vast "unfillable" hall to the exhibitors in the Coliseum of early Chicago show days. The First Regiment Armory was long since made an annex by the now familiar "pneumonia alley" connection, but even its ample floor and galleries failed to satisfy the needs of all intending exhibitors, so that for the first time in its history the basement of the Coliseum has been impressed into service for this purpose, both cars and accessory exhibits being shown. There will be 20 of the former and more than twice as many of the latter thus housed in space never hitherto considered available.

Though not denominated as such, the independent exhibit of purely commercial vehicles which is to be housed in the Seventh Regiment Armory, located at Sixteenth and State streets, about four blocks from the Coliseum, is really another expedient which would naturally be considered as relieving, in great measure, the demands for space in the main buildings, but this has not proved to be the case. As a matter of fact, it is stated that, after mature consideration, the National association decided that the time had arrived for a comprehensive and independent exhibition of commercial vehicles of all types, as that portion of the industry, in many respects identified with the building of pleasure cars, has assumed such importance as to be well able to support a show of its own, giving to the world a much more definite idea of its development and future possibilities than could be obtained where the business automobile was scattered at random among those designed purely for pleasure purposes.

The Seventh Regiment Armory is 353 feet long and 153 feet wide without a post to encumber its floor, so that the thirty odd exhibitors who have taken space in it will have ample opportunity to display their productions to the best effect. It will be known as the First Annual Exhibition of Commercial Motor Vehicles, and though really forming part and parcel of the old show despite its isolation, it has been thought fit to give it a separate title, thus marking the time when the commercial vehicle assumed sufficient importance to warrant separate representation in an independent show of its own.

One admission will entitle the visitor to enter all three buildings, but for the first time in its history the Chicago show will have two high-priced days. These will be Wednesday and Thursday, on which the admission will be raised to one dollar,

**THOMAS HENDERSON**  
President N. A. A. M.

otherwise remaining at 50 cents, as usual. It is not intended, however, to crowd the commercial vehicle's exhibit so as to impede or prevent proper investigation by visitors genuinely interested, the management feeling that it is due to the exhibitors in this department to afford the interested investigator every opportunity to secure all the information he desires. Thus, only visitors to the Coliseum who are sufficiently interested to ask for tickets to the commercial show will be given them. There will be no charge for these admissions, and every effort is being made to secure the attendance of those interested in automobile transportation. Season tickets have been forwarded to department heads of large houses, members of such bodies as the Illinois Manufacturers' Association, and to prominent merchants throughout the country. Each exhibitor has been furnished with as many invitations as he may require for distribution to his prospective customers.

**MILTON J. BUDLONG**  
General Manager A. L. A. M.

### ONLY OPTIMISTS ARE WANTED AT CHICAGO.

A letter was addressed to all those who for business purposes are to be in attendance at the Chicago show. Here is some of the good advice which Manager Miles sent through the mail:

There is no money panic in Chicago; but for the newspaper reports of the doings of Wall Street, Chicago would long ago have forgotten that there had been so much as a ripple. And the great West, about which the East knows so little, is fairly bulging with prosperity.

The agents will be at Chicago; the public will turn out at Chicago. Shall we dampen their ardor by displaying long faces? Or shall we instill confidence and beget enthusiasm by a week of activity, bustle and cheerful bearing?

Your agent in Chicago can get only a certain number of cars, tires, or whatever it is you make. It is his business to make the people understand that to secure early deliveries it is necessary to order now. He can't do it by encouraging the belief that business is poor. Tell him that if he is an agent worth having it is "up to him" to see that his men make every endeavor to influence public opinion in the right direction. And remember that it is equally "up to you."

Let us banish the thought that there is anything wrong with the automobile business. I ask you, in justice to yourself, to your company, and to the show, to carry out and insist that your men carry out this suggestion; that you and they refuse to admit, even to your intimates, that there is any scarcity of business. Leave your troubles at home.

### A. L. A. M. BRANCH TO MEET IN CHICAGO.

A meeting of the Mechanical Branch of the Association of Licensed Automobile Manufacturers will be held during the Chicago show. The principal subjects of the meeting will be the standardization of automobile bodies, co-operation between the automobile engineers and coach builders, the reduction of weight, and proper wheelbase for a practical car.

Representatives of the leading body builders will address the Mechanical Branch meeting and an endeavor will be made toward co-operation between the coach building and automobile industries. The meeting will be held at the Chicago Athletic Club, as it was last year. The following day the engineers will visit the show in a body and make an official inspection of the cars on exhibition.

### A. M. C. M. A. MEETING AT CHICAGO.

The Committee of Management of the American Motor Car Manufacturers' Association will hold an important session at the New Southern Hotel, Chicago, Wednesday morning, December 4. It is understood that the 1908 show question will receive some attention.

### THE CHICAGO AUTOMOBILE CLUB.

The Chicago Automobile Club is just entering upon the fifth year of its incorporate existence. The club was organized in 1902, but it was not until July 2, 1903, that authority was granted by the State of Illinois to incorporate this pioneer western motoring organization. During the first year of the club's existence,

IRA M. COBE, C. A. C.

prior to incorporation, the membership reached a total of about seventy-five. Meetings were held in Steinway hall, and the ardor increased of the devotees of the new sport.

The officers at that time were: President, Arthur J. Eddy; vice-president, F. C. Donald; secretary, Charles T. Jeffery; treasurer, D. David Cottrell. Mr. Eddy soon after left for New York and Mr. Donald succeeded to the chief executive position in the organization.

Plans for the occupancy of a permanent home were early discussed by the club members, and a short time

lease was soon executed for the Hetty Green property at 243 Michigan avenue. Shortly after the occupancy of this building the application for incorporation was made, the signatures on the articles being those of J. A. Ellis, Charles E. Bartley, Robert Tarrant, Jr., and Charles W. Gray. The first board of managers of the club consisted of F. C. Donald, Charles E. Bartley, Robert Tarrant, Jr., Charles W. Gray, W. H. Hoops, Dr. F. C. Greene, J. A. Ellis, F. X. Mudd, S. A. Miles, John Farson, and Dr. F. H. Davis.

John Farson assumed the leadership of the club in the fall of 1903 and was succeeded the following year as president by Ira M. Cobe. Mr. Farson again became president in 1905 and Mr. Cobe again succeeded him in 1906. During this entire period Sidney S. Gorham remained in office as secretary. Mr. Cobe has been re-elected as president for 1907-1908. The new board of managers follows: President, Ira M. Cobe; first vice-president, F. H. Pietsch; second vice-president, T. J. Hyman; secretary, N. H. Van Sicklen; treasurer, C. E. Gregory. Directors: John Farson, T. N. Koehler, A. J. Banta, Claude Seymour, F. D. Countess, W. W. Shaw.

The club's home on Michigan avenue did not long prove adequate to the needs of the rapidly growing organization, and when the temporary lease expired in 1905 it was decided to relinquish the club home for the present and direct all energies toward the construction of the new clubhouse in Plymouth Place. During the intervening period the club occupied rooms.

HOME OF CHICAGO AUTOMOBILE CLUB.

### THE CHICAGO MOTOR CLUB.

A particularly energetic organization has been the Chicago Motor Club, which has been aptly designated as the "do something" club. While it is probably true that the burden of the work has devolved upon a few, it must be stated that the other members have loyally supported, whenever called upon, the various successful events conducted by the club. The president of the organization is one of the pioneers of automobiling in Chicago, F. C. Donald, who, with two other friends, was responsible for the formation of the Chicago Automobile Club. The trio at the time were the owners of the only three gasoline cars in Chicago. Mr. Donald was twice honored with the presidency of that club, which, at the conclusion of its second year, had a membership of over 500 and was comfortably located in a clubhouse.

Mr. Donald was the presiding officer of the Chicago meeting which resulted in the birth of the American Automobile Association. Subsequently he served for two years on the Racing Board and as a member of the Vanderbilt Cup Commission. Treasurer of the National Good Roads Association and of the Chicago Signboards Commission, a director of the New York-Chicago Good Roads Association, and lastly and mostly president of the energetic Motor Club, Mr. Donald is a prominent figure in Western automobiling. Charles P. Root and Secretary George G. Greenberg complete a trio with President Donald which is considered largely responsible for the activities of the Chicago Motor Club.

F. C. DONALD, C. M. C.

### THE ILLINOIS STATE ASSOCIATION.

The Illinois State Association of the A. A. A. recently secured a new president in the person of L. E. Myers, a well-known figure in Chicago automobiling and one of the early members of the Chicago Automobile Club. President Myers succeeded Sidney S. Gorham, the organizer of the State Association, and who was a factor in the passage of the present Illinois automobile law. The State Association, under the leadership of Mr. Myers, is rapidly gaining in membership and several new clubs will be added in the near future. It is expected that before the end of another year the State Association will have grown very appreciably and prove of great benefit to the automobilists of Illinois, which State needs all kinds of roads building. It is the intention of the State body particularly to work for highways improvement, for its directors believe that the day has arrived when the autoists should come out in the open and use every bit of their influence for the betterment of roads. Touring in Illinois, during the rainy seasons of the year, is a wearisome task, for few

L. E. MYERS, I. S. A. A.

of the roads have any bottom and the mud is usually axle deep. In assuming the presidency of the Illinois association, Mr. Myers brings to the task a ripe experience in automobile matters and possesses an accurate comprehension of the great work which can be done for the general good of automobiling by an organization which reaches out to all sections of the State. President Myers will distribute his appointments in such manner as to make all the clubs feel that they are a part of the machinery.

# THIRTY-SIX TO START IN THREE-DAY MUD DRIVE

CHICAGO, Nov. 25.—Almost upon the eve of the start of the Chicago Motor Club's reliability contest, which begins its first day's drive of 230 miles to South Bend, Ind., and return to-morrow, 26 makers have signified their intention of taking part in what is doubtless destined to be a glorious mud rout, by nominating 36 cars. The discrepancy between the number of makers and cars is accounted for by the fact that in a few instances more than one car of the same make has been entered. For example, there will be two Locomobiles, three Mathesons, three White steamers, and two representatives each of the Stoddard-Dayton, Jackson and Pierce-Arrow, both of the last-named being six-cylinder cars. Of this number, 24 are five and seven-passenger touring cars; one is a four-seated tourabout, the Marion, and 10 are three-seated roadsters, the Reo being the only real representative of the runabout class, while the commercial end also has a single representative in the shape of the Rapid 'bus. Under the usual classification the last-named would ordinarily be placed in Class B, the members of which are compelled to average 17 miles an hour, but as this would be manifestly unjust, it will compete in Class C, or the 14-mile-an-hour class.

A review of the tabulated classification shows a total of 18 cars in Class A, cars listing over \$3,000 and which will have to make an hourly average of 20 miles; 12 in Class B, cars listing between \$1,800 and \$3,000, and six in Class C, listing under \$1,800, the last two classes, as already mentioned, having to

travel at an average speed of 17 and 14 miles an hour, respectively. In addition to the penalties incurred during the running of the contest, the cars are to be examined after the conclusion of the three-day run and they will be penalized according to their condition. For instance, wheels spread more than 1-2 inch, five points for each 1-2 inch or fraction; the same penalty for each 1-4-inch sag in springs over the one-inch permanent set allowed; 15 points for each 1-4-inch sag in frame; 10 points for each 1-8-inch variation in steering knuckles; one or more cylinders of motor missing in two-block test, 50 points; failure of brakes to stop car in reasonable distance, 30 points; failure of change-speed gear, either forward or reverse speeds, 50 points; perceptible slipping of clutch, 30 points. This examination will certainly add considerably to the value of the awards.

In view of the size and power of the cars in the first two classes, it may appear strange at first sight that such a low average speed will be required of them, but to any one who is familiar with the roads constituting the route of the three-day contest the fact that even these conservative speeds will call for most consistent running on the part of the contestants, if they are to turn up at the various controls on time, will be recognized. And consistent running will mean strenuous effort on the part of the drivers in view of the bogs and mud-holes that form such a large part of the roads to be traveled over. The list of entrants is as follows:

## CLASS A. CARS LISTING OVER \$3,000. AVERAGE 20 MILES AN HOUR.

Nos.	Car	H.P.	Cylinders	Tires	Entrant	Driver	Observer
17.	Frayser-Miller	50	4	Diamond	Oscar Lear Auto Co.	J. Barnes	R. M. Hess
11.	Jackson	20-24	4	Goodyear	Det. Jackson Auto Co.	F. L. Holmes	W. Diehl

25.	Reo	18-20	2	Michelln	W. W. Shaw Co.	M. D. Vandercar	H. F. Musgrave

## GATHERED AT AMERICA'S NATIONAL AUTO SHOW

COMPARISONS are odious, 'tis true, but it is only by the light of former achievements that progress can be measured, so that it is in no spirit of disparagement that the vast aggregation which will be housed in Chicago by the Coliseum, the First Regiment Armory, and the Seventh Regiment Armory, from November 30 to December 7 this year, calls attention to itself and its size as compared with that of either of the show functions fostered in New York City. Chicago is accustomed to doing big things and calling them bigger, so that the average man who is not of the Windy City must have recourse to the salt at times, but he will certainly not need it where the Chicago show is concerned. If the following statistics of the "Who they are and where they exhibit" order fail to convey an adequate impression, as statistics usually do, the fact that there will be gathered together under the three roofs which have been found necessary to accommodate the aggregation no less than 120 exhibitors of complete cars cannot be other than extremely significant when it is recalled that New York's two shows did not bring together more than 110 all told. In short, Chicago's show is New York's two functions rolled into one, with on the side a very generous sprinkling of manufacturers who do not regard the affairs in the metropolis as within their show program. And how large a "side" this is becomes apparent both on examination of the list of car exhibitors, as well as those in the seemingly

boundless field of accessory making. No further comparison or comment as to proportions would appear to be necessary after this.

Perusal of the list of automobile builders reveals the fact that the "old guard" of the industry is lined up in full force, gasoline, steam and electricity all being well represented, while the showing of new productions, particularly those light cars that are distinctly of American evolution, is such as only the Chicago show can boast of. In brief, here the popular-priced car is to be seen in all its glory and in its widest range of price and perfection.

Accessory makers are here, there, and everywhere, even to the extent of having a separate show of their own in connection with the gathering of business wagons in the Seventh Regiment Armory. No section of the tri-partite gathering of cars lacks its concomitant showing of accessories of everything under the sun for the auto and the autoist. And seldom has such a very comprehensive gathering of manufacturers who devote their attention to the production of the thousand and one things generically known as accessories been brought together at one time. It is somewhat of a misnomer to dub them all accessory exhibits, for, besides the many who make tires, lamps, ignition apparatus, distance-recording instruments, tops, lubricants, and so on *ad infinitum*, there are those who show motors, frames and similar important essentials of the car which cannot be viewed in any light as accessories.

## TIRE ACCESSORIES, TOOLS, AND MISCELLANY.

Auto Pump Co., Springfield, N. Y.  
 Imperial Brass Mfg. Co., 242 So. Jefferson street, Chicago.  
 Leather Tire Goods Co., Newton Upper Falls, Mass.  
 Newmastic Tire Co., 68th street and Broadway, New York.  
 Shaler Co., C. A., Waupum, Wis.  
 Weed Chain Tire & Grip Co., 28 Moore street, New York.  
 Wray Pump & Register Co., Rochester, N. Y.

## COILS, TIMERS, SPARK-PLUGS, ETC.

Atwater-Kent Mfg. Co., Philadelphia.  
 Bemus, T. Alton, Boston.  
 Connecticut Telephone & Electric Co., Meriden, Conn.  
 Duplex Coil Co., Fond du Lac, Wis.  
 Hardy Co., R. E., 86 Watts street, New York.  
 Heinze Electric Co., Lowell, Mass.  
 Igniter Appliance Co., Cleveland.  
 Jeffery-Dewitt Co., Newark, N. J.  
 K. W. Ignition Co., Cleveland.  
 Kokomo Electric Co., Kokomo, Ind.  
 Mosler & Co., A. R., 163 West 29th street, New York.  
 National Carbon Co., Cleveland.  
 Never-Miss Spark Plug Co., Lansing, Mich.  
 Pfanstiehl Electrical Laboratory, North Chicago, Ill.  
 Pittsfield Spark Coil Co., Dalton, Mass.  
 Splittdorf, C. F., 261 Walton avenue, New York.  
 Uncas Specialty Co., Norwalk, Conn.

## DRY AND STORAGE BATTERIES.

American Electrical Novelty & Mfg. Co., 304 Hudson St., New York.  
 Chicago Battery Co., 1400 Michigan avenue, Chicago.  
 Dayton Electrical Mfg. Co., Dayton, O.  
 Electric Storage Battery Co., Philadelphia.  
 National Battery Co., Buffalo.  
 National Carbon Co., Cleveland.  
 Stackpole Battery Co., St. Mary's, Pa.  
 Vesta Accumulator Co., 1334 Michigan avenue, Chicago.  
 Vivax Storage Battery Co., 2224 Michigan avenue, Chicago.  
 Witherbee Igniter Co., 541 West 43d street, New York.

## MAGNETOS AND DYNAMOS.

Bosch, Robert, Inc., 160 West 56th street, New York.  
 Dayton Electrical Mfg. Co., Dayton, O.  
 K. W. Ignition Co., Cleveland.  
 Mottlinger Device Mfg. Co., Pendleton, Ind.  
 Pittsfield Spark Coil Co., Dalton, Mass.  
 Remy Electric Co., Anderson, Ind.  
 Splittdorf, C. F., 261 Walton avenue, New York.

## MAKERS OF AUTOMOBILE PARTS.

Auto Parts Co., 975 Monticello avenue, Chicago.  
 Baldwin Chain & Mfg. Co., Worcester, Mass.  
 Briscoe Mfg. Co., Detroit.  
 Brown-Lipe Gear Co., Syracuse, N. Y.  
 Brownell Motor Co., F. A., Rochester, N. Y.  
 Cramp & Sons, William, Philadelphia.  
 Diamond Chain & Mfg. Co., Indianapolis.  
 Gemmer Mfg. Co., Detroit.  
 Gray-Hawley Mfg. Co., Detroit.  
 Hyatt Roller Bearing Co., Harrison, N. J.

Indestructible Steel Wheel Co., 1303 Michigan avenue, Chicago.  
 Kinsey Mfg. Co., Dayton, O.  
 Long Mfg. Co., 1432 Michigan avenue, Chicago.  
 Muncie Auto Parts Co., Muncie, Ind.  
 McMullen, Roger B., 1241 Michigan avenue, Chicago.  
 Midgley Mfg. Co., Columbus.  
 Shelby Steel Tube Co., Pittsburg.  
 Ross Gear & Tool Co., Lafayette, Ind.  
 Spicer Universal Joint Mfg. Co., Plainfield, N. J.  
 Standard Roller Bearing Co., Philadelphia.  
 Timken Roller Bearing Axle Co., Canton, O.  
 Triple Action Spring Co., 1254 Michigan avenue, Chicago.  
 Prosser & Son, Thomas, 15 Gold street, New York.  
 Warner Clutch Co., 1481 Michigan avenue, Chicago.  
 Warner Gear Co., Muncie, Ind.  
 Western Malleable Steel Co., Detroit.  
 Whitney Mfg. Co., Hartford, Conn.  
 Whiteley Steel Co., Muncie, Ind.

## LAMPS.

Atwood Mfg. Co., Amesbury, Mass.  
 Badger Brass Mfg. Co., 437 Eleventh avenue, New York.  
 Dietz Co., R. E., 60 Laight street, New York.  
 Edmunds & Jones Mfg. Co., Detroit.  
 Gray & Davis, Amesbury, Mass.  
 Ham Mfg. Co., C. T., Rochester, N. Y.  
 Manhattan Screw & Stamping Co., 57th street and West End avenue, New York.  
 Rose Mfg. Co., 910 Arch street, Philadelphia.  
 Standard Lamp & Mfg. Co., 45 South Canal street, Chicago.

## SPEEDOMETERS.

Auto Improvement Co., 316 Hudson street, New York.  
 Hoeffcker Co., Boston.  
 Jones Speedometer Co., 76th street and Broadway, New York.  
 Lipman Mfg. Co., Beloit, Wis.  
 Motor Car Specialty Co., Philadelphia.  
 Oliver Instrument Co., Minneapolis.  
 Smith Mfg. Co., R. H., Springfield, Mass.  
 Stewart & Clark Mfg. Co., 502 Diversey Boulevard, Chicago.  
 Veeder Mfg. Co., Hartford, Conn.  
 Warner Instrument Co., Beloit, Wis.

## BODIES, TOPS, WINDSHIELDS, AND PROTECTORS.

Auto Accessories Mfg. Co., Detroit.  
 Chase & Co., L. C., Boston.  
 Chicago Coach & Carriage Co., 1223 Michigan avenue, Chicago.  
 Chicago Windshield Co., 235 Johnson street, Chicago.  
 Limouline Carriage Mfg. Co., 3515 Michigan avenue, Chicago.  
 Lingdin-Brugger Co., Fond du Lac, Wis.  
 Rands Mfg. Co., Detroit.  
 Sprague Umbrella Co., Norwalk, O.  
 Troy Carriage Sun Shade Co., Troy, O.  
 Vehicle Top & Supply Co., St. Louis.

## LUBRICANTS AND LUBRICATING APPLIANCES.

Cook's Sons, Adam, 313 West street, New York.  
 Dixon Crucible Co., Joseph, Jersey City, N. J.  
 Hancock Mfg. Co., Charlotte, Mich.  
 Harris Oil Co., A. W., Providence, R. I.  
 McCord & Co., Old Colony Building, Chicago.  
 Neeley, Edward, & Co., 244 Wells street, Chicago.  
 N. Y. & N. J. Lubricant Co., 14 Church street, New York.  
 Precision Appliance Co., 840 Austin avenue, Chicago.  
 Randall-Falchney Co., Boston.  
 Robinson & Son Co., W. C., Baltimore.

## SHOCK ABSORBERS.

Gabriel Horn Mfg. Co., Cleveland.  
 Hartford Suspension Co., 67 Vestry street, New York.  
 Hotchkiss Mfg. Co., 1256 Michigan avenue, Chicago.  
 Kilgore Mfg. Co., Old Town, Me.  
 Sager Company, J. H., Rochester, N. Y.

## CARBURETERS.

Breeze Carbureter Co., Newark, N. J.  
 Byrne-Kingston & Co., Kokomo, Ind.  
 Heitger Carbureter Co., 205 West South street, Indianapolis.  
 Whesler & Schabler, Indianapolis.

**UNIVERSAL PROVIDERS.**

Arnstein, Eugene, 36th street and Shields avenue, Chicago.  
 Excelsior Supply Co., 233 Randolph street, Chicago.  
 Franco-American Auto Supply Co., 1404 Michigan avenue, Chicago.

**TOOLS, JACKS, ETC.**

Cook Standard Tool Co., Kalamazoo, Mich.  
 Duff Mfg. Co., Allegheny, Pa.  
 Oliver Mfg. Co., 203 South Desplaines street, Chicago.

**COMPRESSED ACETYLENE TANKS.**

Avery Portable Lighting Co., Milwaukee.  
 Prest-O-Lite Co., Indianapolis.

**PAINTS, VARNISHES, ETC.**

Sherwin-Williams Co., Cleveland.  
 Standard Varnish Works, 2620 Armour avenue, Chicago.  
 Valentine & Co., 277 Dearborn street, Chicago.

 Timken Roller Bearing Axle Co., Canton, O.

**SOME STATISTICS OF THE ONLY NATIONAL SHOW**

IN all, the show will house more than 300 exhibitors, of which no less than 82 are manufacturers of complete automobiles of the gasoline-driven pleasure type, in addition to which there is 1 maker of pleasure vehicles, 7 of electrics and 13 motorcycle makers. In the commercial section of the show there are 23 manufacturers of gasoline-driven vehicles, 1 steam-driven, and 3 makes of electrics, making a total of 130 exhibits of complete vehicles of both the pleasure and commercial classes. There are close to 200 exhibitors of accessories of every nature, including some 18 manufacturers of tires, 31 of ignition apparatus, 28 of automobile parts, large and small, 9 of lamps, 10 of speed-recording instruments, 10 of tops, bodies and the like, 10 refiners

of lubricating oils, and so on down through many minor classifications, ending up with 47 exhibitors of miscellaneous wares.

If it were possible to even approximately figure the value of the cars and accessories shown, it would make a truly astounding total, as the 130 makers stage between 300 and 500 cars of an average value of about \$1,500, while the value of the accessory exhibits ranges from a few dollars up to thousands. Statistics of the materials employed in decorating are no less impressive, as there will be some 9,000 square feet of oil paintings, 100,000 square feet of ornamental work in the ceilings, 20,000 feet of paneled wall covering, 110,000 square feet of carpeting, and three or four tons of miscellaneous staff ornaments.

# TABULAR STORY OF THE AMERICAN AUTOMOBILE

If it were possible to reconcile the many variations of design to be found even in the close approach to a standard that at present prevails in automobile design, and to make a composite of the result, it would doubtless be found that the American car thus produced would be characterized by all those features of design and construction that have come to be generally recognized by engineers as the best current practice. It would be readily possible to construct a composite, or rather composites, taking as the basis of each those cars that fall within certain classifications.

For instance, there is that typical product of the soil, the buggyabout, which has already sprung up in such numbers and taken such a firm hold on the popular fancy of the class of users for which it is destined that there can be no possible doubt as to its future. It is characterized by the use of a single or twin-cylinder motor, almost invariably of the horizontal type, ranging from 4 to 12 horsepower, and with a liberal sprinkling of air-cooled engines among the number. Change-speed gears are mainly of the planetary type, with friction types a very close second, and chains practically a standard form of final drive. Some have single-chain drive, others steel cables—but to run over the exceptions would be out of the question. Where price is concerned \$600 may probably be put down as the average figure.

But while dwelling on cars at this price it must be mentioned that there is the small, single-cylinder runabout at one end of it and the four-cylinder high-speed runabout at the other, which only goes to show that even when adhering to a particular classification it is extremely difficult to evolve a composite that shall reflect the features of all its component parts. In brief, there are too many American cars that are in a class of their own to make such a division practical or of any value. A price classification brings all these small cars in the "under \$1,000" division and it is noticeable that there is far more diversity within this limited price range than is to be found among the cars costing several times as much, for it is mainly in the high-priced cars that the effects of standardization are apparent.

In the \$1,000 to \$2,000 class there is quite as much diversity as in the initial price division, such extremes as the single-cylinder, 10-horsepower car and the four-cylinder, 20-horsepower car being found at the first-named figure, while the addition of \$150 to \$250 brings with it a number of vehicles of far more ambitious

size and appointments, though even at the \$1,000 line there is a wider choice permitted the prospective purchaser than has been the case in past years, as, in addition to two single-cylinder 10-horsepower cars at this price, he will find two representatives of the 20-horsepower four-cylinder type and two of the 18-horsepower two-cylinder opposed type.

Price increases are marked by small jumps—as low as \$25, and not exceeding \$100, until the \$1,850 line is reached. Between \$1,000 and the last-named figure there is a wide choice of vehicles designed expressly for American road conditions and capable in large measure of all that their far higher-priced and higher-powered confreres can perform in the shape of endurance and "get-there" qualities, which are sought for by the American buyer above all things. In the lower limits of this division the planetary gear and chain drive prevail, with a scattering instance or two of the friction type, then emerging into the borders of higher standards in the shape of sliding gears and shaft drives, with frequent instances of selective types of gearboxes. Here also are met the air-cooled car and the two-cycle, though these are also to be found under the \$1,000 mark.

But it is in the \$2,000 to \$3,000 class that the American car becomes at once the pride of its builder and owner, and the despair of the foreign manufacturer, who finds it impossible to build a competing model to sell at the lower limits of this classification and can barely succeed in squeezing his lightest models in at its upper line of demarcation. Here standards at once become more uniform, and differences far less striking than is the case in lower-priced constructions, where financial limitations apparently act by contraries in giving far wider latitude of design. In both this and the next classification of \$3,000 to \$4,000 it would not be particularly difficult to construct a composite that would accurately reflect the characteristics of its numerous components. As a matter of fact, from the \$2,000 mark upward it is really but a question of more expensive materials, higher-priced accessories, some of which figure as "extras" in the lower latitudes, and more luxurious equipment and finish, so that the salesman's oft-repeated litany of "vertical motor in front, sliding gear, direct on the high, shaft drive," etc., suffices to cover their salient features fully as well as any extended description possibly could. A price limit is really reached at \$6,000, but a few straggling along to the \$10,000 figure.

## COSTING LESS THAN \$1,000

CAR	Price	H.P.	Cylinders	Body	Seats	Ignition	Clutch	Transmission	Drive	Wheel-base	W'ght

# QUICK-CHANGE TIRES TO THE FORE

By W. F. BRADLEY.

THERE was a time when it used to be a pleasure to the automobilist to "fix things." There was as much satisfaction in surmounting difficulties which cropped up from time to time as was obtained in a smooth, easy-going ride; indeed, half the pleasure of motoring came from a knowledge that you had been able, despite an inherent cussedness of the thing, to keep the machine going. That heroic phase of the sport passed away some years ago, and the motorist to-day is apt to be as unreasonable when something goes wrong as he was cheerful at more youthful seasons. Even tire troubles are not accepted with anything like the same degree of resignation as formerly, the ominous hiss of escaping air generally being greeted with a muttered curse instead of

MIDGLEY RIM WITH DUNLOP

the whistling of a cheerful air as the driver pulls off his coat. Some day, doubtless, punctures will become as extinct as the dodo; while waiting for the good time coming the automobilist who no longer loves to tinker is accepting quick-changing devices with gratitude and giving thanks for blessings to come. Whereas quick-change tires were formerly treated as an accessory and were always paid for extra by the purchaser of a car, they now form part of the standard equipment of nearly all the higher-priced automobiles. At the Madison Square show about 60 per cent. of the cars were shown with some of the better-known quick-change rims as the standard equipment; doubtless, too, most of those firms in the minority would include any of the standard devices without extra charge if requested to do so by a customer. The 1908 season is remarkable for the unanimity with which the industry has accepted the inventions of the tire firms for facilitating changing of tires.

Of the two classes before the public—quick-detachable and dismantlable, as they are variously called—the former is by far the most popular for ordinary use. While making the changing of a tire much more simple and less arduous, it has the advantage of not requiring the carrying of any extra parts and adds nothing to the weight of the wheel. Some care has still to be taken in fitting the inner tube and the pump has to be brought into use; with a mechanical pump or a really portable compressed air tank, such as is promised already, the standard types of quick-detachable rims at present on the market would be practically perfect and would leave little room for the dismantlable for ordinary

TWO TYPES OF MIDGLEY RIMS

touring. For speed work the dismantlable rim is undoubtedly superior; when a change of tire is necessary the wheel is jacked up, half a dozen nuts slackened, rim and tire pulled off together, a new rim with previously inflated tire substituted, the nuts tightened up again, and the journey continued. Carrying a spare rim and inflated tire adds to the weight of the car, and is consequently not looked upon with full favor by the average automobilist. There seems to be an impression, too, that the dismantlable type is not altogether safe, though how unfounded

this fear is long-distance speed tests have clearly proved, speeds of over seventy miles an hour having been maintained by cars fitted with all the prominent makes of dismantlables without any weakness being developed. As it becomes better known, and is brought more prominently before the public by the manufacturers, doubtless the dismantlable will run the quick-change type of tire closely for popular favor; at present, however, tourists are most closely interested in the appliances designed to allow of tires being changed with increased facility by the removal of the outer bead or clincher, and are prepared to do work on the road whenever necessary, provided it does not call for much physical effort or demand any special skill.

## Some Standard Types of Quick-change Rims.

Having been adopted by such well-known tire firms as G & J, Hartford, and Morgan & Wright, and forming the standard equipment of many automobile manufacturers, the Midgley universal rim has secured a strong position in the world of quick-detachables. Instead of the outer clincher forming an integral part of the rim, it is a separate ring, fitting in a groove on the outer edge of the rim, with its two ends united by a turnbuckle.

SECTIONAL VIEW MARSH RIM.

A glance at the illustration shows the simplicity of the arrangement and its ease of manipulation, all that is necessary to dismount or remount the bead being a few turns of the improved turnbuckle, the only tool needed being a little crank wrench. When required for Dunlop tires, the inner clip is filled with an endless band of rubber and the outer ring is reversed, the method of fastening remaining unchanged.

In the Marsh rim, now manufactured and marketed by the Diamond Rubber Company, the mode of attachment is a removable steel flange and a split locking ring with a curved lip fitting snugly over the projecting base plate. A wedge-shaped piece of metal fits into place between the open tapered ends of the ring, spreading it so that there is no possibility of its coming off. To give still further security the keystone locking part is itself held in place by being attached to a bolt on the main rim body and held there by a nut. An open end wrench is supplied for pulling off the locking ring when the wedge plate has been removed; the tool is not absolutely necessary, however, for with the removal of the wedge the split ring can be forced off without difficulty by inserting the point of a screwdriver. With the Diamond wrapped tread tires no stay bolts are required for use with the detachable rim, and the operation of changing an ordinary tire by a person with moderate experience need not exceed five minutes. When any regular clincher tires made for one-piece rims are employed, however, stay bolts become a necessity. Interchangeable rings are provided, by the use of which Dunlop type of tires can be used with the Marsh rim, the labor of attaching or detaching being substantially the same as for the clincher

DETAILS OF MARSH.

GOODYEAR RIM AND SPREADER.

or channel on the outer edge of the plate, thus securing the outer ring. A spreader plate attached to the valve stem is the only locking arrangement, the screwing up of a rim nut pressing the flange against the split portion of the locking ring so that it cannot be lifted out or removed from the channel by any strain whatever. The single nut on the valve stem being the only fastener, no tool is required for use with this rim; it will be obvious that the thumb nut on the valve stem must be maintained tightly secured up to insure safety. This is guaranteed by the valve cap, which, when in position, acts as a check nut. One of the claims of the Goodyear rim is that it is absolutely impossible to rim cut when running flat, for the flanges are round instead of sharp, and form the arc of a two-inch circle. By substituting clincher flanges in place of those shown in the illustration, the universal rim can be used for Goodyear clincher or any standard G & J tire.

In the Fisk mechanically fastened tire there are structural differences in the casings which are not found in other types. The base of the tire is flat, formed of a tough, heavy cushion of rubber and fabric composition. This flat base rests on a steel rim, with a corresponding flat surface, and is secured there by two wedge-shaped galvanized steel rings, which set in over the rubber base head. The rims are secured in place by galvanized clamps and bolts passing through the felloe, which grip them solidly to the flat rim, the tire and rim then being as one piece of mechanism, impossible to loosen accidentally.

SECTIONAL VIEW OF FIRESTONE RIM.

In the Firestone universal rim is another example of the class adopting a fixed steel base with a raised inner edge and a groove or channel on the outer edge. A couple of flange rings slide onto this, the inner being held by the projecting edge and the outer one by the locking ring, equipped with a hole at each end to slip over a couple of pins projecting from the flange. On the valve stem is a

COMPONENT PARTS OF REPUBLIC.

metal plug or spreader, which fits into the base of the channel, thus holding apart the walls of the tire and the two removable rings. When Firestone clinchers are to be used, all that is necessary is to change the flange rings for those of clincher type. Standard clincher tires can be used with the rim by drilling the felloe and equipping with stay bolts.

The Republic detachable rim, intended specially for use with the Republic tire, has certain peculiarities in the design of the removal bead and locking ring, as well as in the base of the tire easing. This latter forms a perfectly cylindrical tube, without any crevice or crack in which the inner tube can be pinched. The locking ring is of U section, made to fit over the turned-down edge of the base plate and the heel of the removable flange; a wedge-shaped key piece is inserted in the split ring and secured by three cap screws.

Distinctive in the Goodrich quick-detachable tire is the securing of the split ring by two substantial hooks of almost square section. These ends are dropped into the longer and innermost holes of a slot on the base plate, then forced outward into the smaller ones, which they completely fill. A special tool is provided for this purpose. The dust cap for the valve is made to act as a retainer, so that the tire does not creep and is prevented from being blown off, whether inflated or otherwise.

MICHELIN DISMOUNTABLE RIM.

Some of the Leaders in the Dismountable Field.

In the six or seven types of dismountable rims now on the market the problem has not been to produce a new method of attaching the tire to the rim, but to produce a double rim, one fitting over the other, which would give the maximum safety with minimum weight. The tire and method of attaching it to the rim are in no way changed, the usual clincher attachment being almost universal. Naturally some provision had to be made for the stay bolts, as well as for the valves, for it was manifestly impossible to fix a dismountable rim over the wheel with these projections. The usual plan is to cut the stay bolts short, some makers countersinking them on the dismountable rim and supplying special tools for their withdrawal, others cutting them as short as possible, so that they would fit in the limited space between the two rim surfaces. In the same way with the valve, there have been attempts at countersinking this, with a special valve connection for inflation, which could of course only be used when the rim was dismounted; others have retained the ordinary valve, making either a hole or a notch in the felloe for its accommodation.

SECTION OF MICHELIN FASTENER.

One of the earliest of dismountable rims to be put to practical service in speed tests was the Michelin, now manufactured at that firm's American factory. Here the tire is carried fully inflated on a dismounted rim, ready to be fixed over the wheel when required. The rim placed in position on the wheel, it is secured from rotary movement by a couple of stops and held secure by eight plates fitting over a corresponding number of bolts passing through the felloe. A strong claim for this rim is that the fasteners not only slip between the two rim surfaces, but are curved to embrace the round section of the dismountable rim, each fastener being held

NEW DIAMOND DISMOUNTABLE.

by a nut on a heavy bolt passing through and secured in the felloe. A special magazine brace is furnished with the Michelin dismantable rim, by the use of which it is never necessary to handle the nuts with the fingers, each one passing into the magazine and presenting itself for use as soon as the brace is placed over the bolt.

Quite recently the Diamond Company has produced a demountable rim, in which the stay bolts and valve stem come flush with the surface of the rim. Provision, however, is made for inserting a special connection through the felloe to the valve if it is

necessary to inflate the tire when mounted on the wheel. On the dismantable rim are six projecting lugs with eyeholes which fit over bolts projecting from the face of the felloe when the rim is mounted on the wheel. A nut on each secures the two from movement. There is no danger of binding, for, as will be seen from the illustration, only a portion of the two surfaces comes into contact.

In addition to their quick-detachable, the Fisk Rubber Company has also a removable rim. The wheel is fitted with a special steel rim, one edge of which is flanged to provide an abutment for the tire rim, the other edge being beveled to provide a recess for a specially constructed expanding ring. Both felloe and expanding ring are pierced at intervals by bolts fastened so that they cannot fall or turn. When the removable rim with its tire is placed in position, the nuts on the bolts are tightened, the ring expands into the beveled groove of the wheel rim, holding the removable rim tightly in place. To remove the rim, all that is necessary is to loosen the nuts, which causes the expanding ring to contract and the removable rim is readily slipped off.

On the Crescent dismantable rim the bearing points are two beveled edges of the fixed and removable rims, made of rolled carbon steel, galvanized. Six hinged clips are permanently secured to the felloe, each one being provided with a bolt and nut. Changing is materially facilitated by the hinging of the clips, the rim being dismantled by the removal of the six nuts.

On the inner face of the Firestone dismantable rim are six projecting square steel stops corresponding with the same number of openings on the face of the fixed rim. The operation of mounting consists in slipping the movable rim over the fixed one with the stops in position to correspond with the grooves, imparting a slight rotary movement, and screwing up the six face plates on the felloe, so as to hold both rims. By this arrangement the rim is given six points of attachment against lateral and rotary movement.

Although newly introduced into this country, the demountable rim manufactured by the Continental Caoutchouc Company is one of the oldest in existence, having been successfully used in European races nearly three years ago. The

inner edge of the fixed rim is beveled to form an abutment for the dismantable one, the outside support being eight wedges fitting over as many bolts passing through the felloe, each one being secured by a nut. Special stay bolts are employed, but the valve is of the ordinary type, an opening having been made for it in the felloe.

Conversion of ordinary road wheels to the dismantable type can be effected with nearly all the types described here, the operation being a comparatively simple one and not costly. If the felloe is of sufficient thickness to allow of it being planed down, it may be retained, though as a rule it has to be taken off and the spokes

shortened. A new felloe is then fitted and bound with a special metal rim designed to accommodate the dismantable rim. Six to eight bolts have to be put

CRESCENT DISMOUNTABLE.

through the wood felloe to correspond with the lugs or other fastening on the dismantable part. Where an ordinary valve is used this also has to be provided for by an opening on the face of the felloe. As regards security the converted wheel is just as satisfactory as those specially built for the improved type. To obtain the full benefit of dismantable rims, some attention should be paid to their cleanliness, dirt

CONTINENTAL DEMOUNTABLE RIM.

being removed from the screw heads when the car is washed, and the thread greased when a rim is dismantled. When mounting, too, it is necessary to observe that the nuts are tightened up gradually in opposite pairs in order that the pressure may be equally distributed.

### THE LARGEST SOLID TIRE AT THE SHOW.

An interesting feature of the commercial vehicle section of the exhibit of the Firestone Tire & Rubber Company, of Akron, O., at the Chicago show, will be one of the largest solid tires ever exhibited. It is one of the Firestone Dual motor tires, measuring 53 1-2 inches in diameter, and will be shown with the business wagons for which it is intended, together with the other Firestone commercial tires, such as the endless and butt-end forms of both the side-wire and dual tires. In connection with the pleasure cars, the same company will show its line of quick-detachable, clincher and mechanically fastened tires and the 1908 Firestone dual tread and dismantable rim. Copies of the "Chauffeur's Moral Code," intended for the guidance of the drivers of commercial vehicles, will be distributed.

FIRESTONE DUAL TIRE.

DISMOUNTING THE FISK RIM.

INTERIOR OF OLYMPIA, LONDON, WHERE GREAT BRITAIN'S GREAT AUTOMOBILE TRADE IS EXHIBITING THE PRODUCTS OF ITS CONSTRUCTIVE GENIUS.

## NEWS FROM BRITAIN'S AUTO SHOW AT OLYMPIA

LONDON, Nov. 13.—Olympia show should certainly be a big success this year from the salesman's point of view, for the multiplicity of provincial exhibitions which in former seasons have both drained the resources of the manufacturer and protracted the purchaser's efforts, have now been cut off by the Society of Motor Manufacturers and Traders, and but one other British show will follow Olympia, namely, at Manchester, in February next. The official opening of this, the largest yet of British motor exhibitions, was performed on Monday by the Duke of Connaught, who came down in his own car. This royal recognition of the movement is likely to be further emphasized, for, at the time of writing, the Kaiser is confidently expected to visit the show incognito, and it is not likely that Spain's motoring monarch will omit a visit before his departure from these shores.

A walk around the show at once confirms the opinion so prevalent of late. The reports of the over production of all the Continental firms was strongly contradicted by their agents. The new prices for 1908 season, however, tell their own tale. There is hardly a car of French or Italian make but shows a considerable reduction from previous prices—in some cases as much as £100 being marked off models which are unchanged in form from those of the past season.

### Tendencies Evidenced in the New Models.

There are quite a number of interesting tendencies other than the main feature of price reduction mentioned above. The six-cylinder engine has gained many adherents even in the lowest powers—in several cases the rating being but 15 horsepower. The two and three-cylinder engine has been replaced by the four-cylinder type, leaving the single-cylinder engine to the smallest voiturette. The practice of casting the four cylinders in one block has grown greatly in favor, and on quite a dozen stands this short form of engine is shown. Casting in pairs is usual in other cases, comparatively few engines having separate cylinders. A distinct advance—from the user's point of view—has been made by the general placing of the crankshaft bearings in the upper half of the crankcase, enabling the lower half to be readily removed for inspection of the connecting rod ends.

Magneto ignition steadily advances in favor, particularly the high-tension variety, and even where not fitted standard, it is readily obtainable at slight extra cost. Several firms have caused surprise by abandoning the low-tension magneto for the high-tension variety, Thornycroft, in particular, having given up their well-tried system.

The general adoption of mechanical forms of engine lubrication was a prominent feature of last year's show and now comparatively few cars are found with the exhaust pressure drip feed device. On the lower priced car the drip feed is maintained, but the oil is supplied by means of a pump, belt-driven from the engine. The larger cars have almost invariably a gear-driven pump inside the crank chamber, drawing the oil from a well and forcing it through the main bearings. The nuisance of over lubrication is fast being obviated; as opposed to the general method of using an overflow, the Belsize car has a large, foot-operated pump, by which a pint or so of oil can be drawn from the crankcase whenever the engine shows a tendency to smoke.

Probably owing to the present general use of so many spirits of widely varying density, many firms have gone back to the hand-operated air lever, rightly considering it impossible for any carbureter to account for the combined effects of the many factors which enter into the question of a perfect mixture. Where the automatic carbureter is retained, the multiple type, in which the jets come successively into use as the engine speed rises, is growing in popularity. Frequently there is provision for admitting pure air into the cylinders when the engine is used as a brake in descending hills, thereby effecting a distinct fuel economy.

As regards frames, the tubular variety has been abandoned by everyone except the DeDions, and the only rival of the pressed steel frame occurs in the few instances where armored wood is adhered to. Many British makers prefer tubular cross members for their frames. In springs, on the other hand, there is more divergence of opinion. The three-quarter elliptic type of rear spring is found frequently on moderate powered cars, while even on the lowest priced four-seated cars the transverse rear spring is fitted. The use of shock absorbers has not spread, and in comparatively few cars are these fitted as standard.

### Multiple Disk Clutches Growing in Favor.

Turning to the transmission gear, the multiple disk clutch has grown considerably in favor, while the various types of expanding and contracting metal to metal clutches are rapidly dying out. Many British makers have adopted the well-known Hele-Shaw disk clutch, in which the disks are corrugated in section and alternately hard phosphor bronze and mild steel, the pack running in thin oil. The Italians, on the other hand, prefer the old Weston type of flat plate clutch, the disks being either all steel or else brass and steel. The use of a clutch brake for retarding the gearshaft when changing up has grown in favor, particularly when the large, leather-faced clutches are used.

Ball bearings are almost universal for gear boxes; in fact, everywhere except in the engine, the ball bearing has come into general use. Several makers this year have adopted ball bearings for the crankshaft; on the other hand, the Hotchkiss cars, which were the first to adopt these bearings for the engine, will use plain bearings in future.

The provision of four indirect speeds is not now in favor; usually the third speed is made "direct," leaving the fourth speed rather high for use under specially favorable conditions. Some cars have arrangements of double bevel wheels in the differential, whereby direct drive on both third and fourth speeds is obtained. The gate change speed is now everywhere fitted and there is practically no British car of note which, like the Delaunay and the C. G. V., retains the old "straight through" quadrant. More attention is being paid to the protection of the striking gear from dust and mud and various are the interlocking devices which prevent the use of the reverse, while a forward speed is in gear.

A great decrease in the number of chain-driven cars is readily apparent, and so strong an upholder of the chain as Daimler now shows several "live axle" models. Where the chain is used, and this is only in high-powered cars, chain cases are frequently seen, the majority of these being substantial and oil-tight articles which

WHITE STEAM CAR FITTED WITH LOUIS XIV COACH BODY.

INTAKE AND EXHAUST SIDE OF THE SIX-CYLINDER SHEFFIELD SIMPLEX MOTOR.

will permit of the chain running in lubricant, so that the chief objection to the double chain drive of the average user, which is founded upon the dirt-gathering propensities of the chains, has been overcome. A rather interesting tendency in some live axle cars is the provision of a substantial casing round the propeller shaft which serves as a radius rod and greatly simplifies the rear part of the chassis.

Brakes have not received very much attention, but there is in some cases the provision of both sets of brakes on the rear wheels themselves, removing the usual strain from the transmission gear. With a similar end in view, a few cars have the foot-operated brake acting on the rear wheel drums, while the countershaft brake is worked by the side lever and intended for use in emergencies only.

The final point of note—that of wheels—shows a distinct tendency towards the adoption of the wire wheel, Napier in particular offering them on all models. These wheels certainly seem to possess distinct advantages over the wooden artillery type, and if public opinion can only be got to agree to the change, many makers will be ready to adopt the wire wheel by the time of the next show.

More interesting, perhaps, than a résumé of the general body of exhibits, is a brief description of some of the most representative cars. Daimler and Napier are the names which first suggest themselves, and it would be hard to find two such equally popular cars which differ so much in main details. The Daimler firm still adheres to the slow-running four-cylinder engine with the cylinders cast in pairs, the 42-horsepower model having a stroke of 130 by 150 mm., and the 58-horsepower (note the exactness of the rat-

ing) no less dimensions than 155 by 140 mm. The normal engine speed of both these engines is 650 revolutions per minute. The camshafts and valve gear are now inclosed, thereby removing the principal objection which always existed in Daimlers from the mechanical point of view. In place of the single trembler coil and high-tension distributor formerly used, four single non-trembler coils are now placed directly over the engine, but a few inches of wiring being necessary. An auto-trembler device is inserted in the battery circuit and this is in continuous operation. In the 42-horsepower model, the drive is taken through a leather-faced cone clutch to a long speed gear box in which the third speed is direct. Worm drive takes the power to the chain countershaft, a double arrangement of worms and worm-wheels necessitating

but a single gear reduction on the indirect speeds. The 58-horsepower model has four indirect speeds and bevel drive to the countershaft. Both these cars are provided with efficient chain cases, with which are combined radius rods and eccentric bosses for adjustment of the chains. Right up to the opening of the show, the public confidently looked for the production of a low priced and moderate powered Daimler car. This has not made its appearance, but two new live axle models are provided. These cars have respectively bore and stroke of 110 by 130 and 125 by 130 mm., being rated at 30 and 38 horsepower. The gear boxes have four speeds with direct drive on third. The propeller shaft is provided with universal joints at both ends. The rear axle casing is built together in two halves and the horizontal joint is then welded together by oxy-acetylene process. The differential can be removed through an opening forward and

MAGNETO AND WATER INTAKE SIDE OF 45-HORSEPOWER SHEFFIELD SIMPLEX MOTOR.

the driving shafts are withdrawn through the road wheel hubs. What might possibly be considered a defective point of design is the absence of radius and torque rods, both these duties having to be performed by the rear springs. The only other matter for possible criticism is the single control lever on the steering wheel, which actuates both spark and throttle. The general tendency makes for the separation of these two controls, and it would certainly seem impossible to get absolutely best results from an engine in which the ignition is advanced only with full throttle. The price of these cars is £620 for the 40-horsepower, £695 for the 38-horsepower, and for the remaining chain-drive models of 42 and 58-horsepower, respectively, £700 and £925, all prices being for cars complete with standard bodies.

In contrast to the Daimler, the Napier has, of course, the high-speed six-cylinder engine with live axle drive. While retaining the 40 and 60-horsepower models, which have gained such a reputation for themselves during the past two seasons, the Napier stand includes the new 30-horsepower six-cylinder model, which at the chassis price of £575, brings the high-grade six-cylinder car within the reach of an entirely new section of the motoring public. This car is built exactly on the lines of its bigger fellows and, except by the absence of a few refinements, it has lost nothing in the cheapening. The engine has cylinders 102 by 102 mm., with valves all on one side. A new semi-automatic carbureter provides the mixture, its action being automatic as regards the variation in engine speed, but having a hand-operated air lever to enable the use of various grades of petrol. An excellent system of forced lubrication feeds all

M. & M. C. SIX-CYLINDER, 35-40 HORSEPOWER MOTOR, MAGNETO SIDE.

bearings, while the splash oils the cylinder walls. Great attention has been paid to the lubrication of the other parts of the car and every single spring, shackle, and joint has its screw down greaser. The power from the engine is transmitted through a multiple disk clutch with flat steel disks and a flexible joint couples up to the three-speed gearbox. The gearbox shafts are short and have, in addition, a third inside bearing, so that no whip of the shafts can take place. When the top or direct drive is engaged, the secondary shaft is quite idle and does not revolve. Ball bearings of large size are fitted throughout the gearbox and transmission gear. Special attention has been paid to the springing and brakes and, taking every point into consideration, this Napier 30-horsepower may be called the most interesting British-built chassis to be seen at the show.

The Crossley car is the production of the famous gas engine concern of that name, and has the additional advantage of embodying much of the practical experience of Charles Jarrott, who holds the selling rights. The characteristic features of the single model—40-horsepower—is the accessibility of every part and the ease with which any portion of the transmission gear may be removed without disturbance of the adjacent members. The four-cylinder engine is cast in pairs and has bore and stroke of 120 by 150 mm. The carbureter is an improved form of the Xenia, with extra air inlets operated by a piston floating on mercury, the level of which is raised or depressed according to the varying pressure in the induction pipe. The clutch is one of the few remaining examples of the internal expanding metal type and the gearbox is remarkable in that its casing is cast in one piece,

SIX-CYLINDER, 60-HORSEPOWER BRITISH MERCEDES MOTOR, INTAKE SIDE.

DUNLOP DETACHABLE RIM.

the main and lay shafts being inserted from the rear end. Oil-tight joints are arranged at the end bearings, and the gears can therefore be run in oil without undue leakage taking place. The same gear pump which effects the force lubrication system of the engine keeps the gearbox supplied with oil. In the back axle, the differential can readily be withdrawn without removing the body or the axle itself. But it is not so much in distinctive points as in general excellence of workmanship and attention to details that this car is noteworthy, and at its price of £800 ready for the road it will without doubt find a good following during the coming season.

Similar praise might be accorded to the Austin cars, the comparatively new productions of the designer of the early Wolseley cars—those marvels of reliability. The 18-20 and 40-horsepower four-cylinder cars and the 60-horsepower six-cylinder model all follow standard lines, with special reference to accessibility of valves, pump and carbureter. On the 60-horsepower, an interesting feature is the provision of two magnetos. The ordinary magneto (Simms-Bosch high-tension) will run the engine well at very low and at normal speeds, but for high speeds above 1,500 revolutions per minute (and this well-balanced engine can attain over 2,500 r. p. m.) the second specially wound magneto is switched into use and runs the engine till speed falls to normal again. By this method, it is found possible to run the car on top gear through a most remarkable range of speed. A special system of lubrication through the hollow crankshaft to the main and connecting rod bearings is worked by two gear-driven pumps, which draw the oil from either end of the crankcase, so that the lubrication is efficiently performed when the car is on the steepest grades as well as when the oil supply is low.

To meet the "all-British" demand, the new Fiat works at Wembley were expected to have produced home-built Fiat cars by this time, but these have not put in an appearance, nor has the British edition of the Metallurgique, the well-known Belgian car. There is on view, however, a 45-horsepower Mercedes made in London under license and exactly following the lines of the Cannstatt production. As a matter of fact, the Daimler-Mercedes

M. &amp; M. C. DIFFERENTIAL HOUSING.

car has been built at Sheffield for some time, but this is on somewhat distinct lines from the Mercedes proper. One other new departure is the Birmingham built Lorraine-Dietrich. This 20-30-horsepower car has four-cylinder engine with 90 by 120 mm. cylinders cast in pairs. The ignition is low-tension magneto and can be advanced by sliding the roller ended tappets along the

face of the cam. Some 60 flat plates are found in the clutch; these have no separating springs but are each slightly bent. When the pressure is upon the plates, they are flattened out and transmit the power, but as soon as the clutch pedal is depressed, the plates jump into their bent shape and so free themselves. The four-speed gearbox has direct drive on third, and all the striking gear is inclosed, so that no part of it can be deprived of lubrication. The propeller shaft is surrounded by a pressed steel casing which acts as torque and radius rod and also retains the lubricant for the universal joints of the shaft itself. Two independent radius rods are also provided, these being pressed steel of girder section. The rear wheels are canted outwards somewhat at the top, and for this purpose the driving shafts are provided with universal joints at their inner ends. Complete, this car sells at £550, and should serve to maintain the reputation held by the French chain-drive Dietrich models.

The Siddeley cars now include in their number a low powered model of high grade which well meets the demands of that section of the public, whose car, though low in price, must be a four-cylinder model of good construction and fair speed. The new 14-horsepower Siddeley (which the makers alternately list at the R. A. C. rating of 20-horsepower) has cylinders in pairs, the bore and stroke being 90 by 102 mm. The valves are operated by a camshaft and cooling is by thermo-siphon circulation, without pump. The power is transmitted through a leather clutch to a three-speed gearbox with gate control, whence a double universal jointed propeller shaft takes the drive to the rear live axle. This is formed of tapered, flanged, drawn steel tubes, the weight of the car being carried on the sleeves. The chassis scales at but 1,650 pounds total, and its price of £320 attracts much attention. The other Siddeley productions range up to the six-cylinder 45-horsepower car at £850, which model is owned by the Queen for her special use.

#### What Is Shown in the Lower-priced Types.

Round the £300 price are numerous other well-made cars, all strongly similar in construction and of such equal value that the intending purchaser is hard pressed to make his selection. Calthorpe, Bell, Alldays, and a dozen others all fulfill this need, for it is perhaps in this particular department that the British maker has specialized with best results. Mention might be made of the Star 12-horsepower car which gives a well-constructed four-cylinder engine, with magneto ignition and a special multiple jet carbureter and, unusual in so low powered a car, an indirect fourth speed, while the price, with five seated body, comes out at but £300.

The Humber is without doubt the most popular car in Britain and therefore deserves some attention. The firm runs two distinct works: at Beeston, the higher powered cars are produced, the new season's models being the 30-horsepower and the 20-horsepower. The 30-horsepower model is nearer 45-horsepower than its rated power, the bore and stroke of the four-cylinder engine being 120 by 150 mm. Two magnetos, high and low tension, are employed, disposed on opposite sides of the engine. The H. T. magneto is carried on a rocking cradle by metal straps and is capable of being rocked about the armature shaft, thereby advancing or retarding the ignition. The lubrication is effected by gear pump through the drilled-out crankshaft. The drive is transmitted through a Hele-Shaw clutch, with an ingenious form of gearshaft brake which does not come into action when changing down. Ball bearings are fitted in every possible part of the transmission gear. Special attention has been paid to the brakes, which are all easily adjusted by hand, and it would be impossible to find a more powerful speed arrester than the countershaft brake, while for the back wheel brakes an ingenious differential movement introduced into the rod system insures perfect equalization of action. The price for this car, with body complete, is £575. It is interesting to note that this model is evolved from the car that won the last Heavy Tourist Trophy race, while from

VALVELESS 20-HORSEPOWER, TWO-CYLINDER MOTOR.

the Beeston car that ran second in the Tourist trophy itself the present 20-horsepower car has been designed. The engine has four separate cylinders with twin magneto ignitions, high and low-tension. With cone clutch, four speeds, and ball bearings everywhere except in the engine, this car sells, complete, at £424.

It is the Coventry Humber car, however, that has secured the greatest success, and the 10-12-horsepower model might well be claimed the most popular European car yet built. To replace last year's 10-12-horsepower the new 15-horsepower model has been brought out, listed at £315, complete with body and full kit of tools. The four separate-cylindrical engine has 95 by 115 mm. bore and stroke and develops about 24 horsepower maximum. The engine relies on splash lubrication, but on a separate model, slightly higher in price, an efficient forced lubrication system is fitted. The gearbox has three forward speeds with direct drive on top. Both shafts run on ball bearings and control it by gate change, the knot on top of the gear lever rocking inwards to operate the reverse catch. In the rear axle the wheels run on sleeves on the axle casing, the drive being transmitted through outside dog clutches.

This car is undoubtedly excellent value, but the big Coventry Humber feature and the car which is expected to keep busy the new Humber works at Coventry—the biggest in the world—is the small 10-12-horsepower model. This engine has four separate cylinders, 84 by 96 mm., with splash lubrication and accumulator and coil ignition, the commutator being driven vertically and brought to a convenient position on a level with the tops of the cylinders. The frame is of channel steel, with tubular cross members. The clutch is leather-faced and self-contained, the pressure

STRAKER &amp; SQUIRE FOUR-CYLINDER 16-20 H.P. MOTOR.

being given by three coiled springs which pull on a ball thrust ring on the crankshaft. The gearbox gives three forward speeds and reverse operated by a gate lever and, as in the back axle, ball bearings are employed throughout. The brakes are well looked after, and the control levers are brought up to sectors on the wheel. With side-entrance body, supported upon an additional transverse spring at the rear, and with full kit of tools, the price is £250—as low a figure as is likely to be reached for some time to come.

There are, of course, two-seater cars with single-cylinder engines, in price down to £130, but, with the exception of the little Rover and the Riley, the British makers have left the production of small voiturettes to the French and have preferred to interest themselves with the light type of four-cylinder cars with four-seater body.

### ENGLISH VANADIUM STEEL FOR AMERICAN CARS.

Vanadium steel having come to be regarded as the highest standard for automobile construction is now largely employed in many of the best-known American cars, and the demand for it has led one of the oldest English mills to enter the American market. This is the Ferry Works of Willans & Robinson, Ltd., situated at Queen's Ferry, S. O. Flintshire, England. G. F. Ehrenzeller, the Pennsylvania Building, Philadelphia, Pa., has taken the sole agency for the United States and Canada, and has been recently sending the trade illustrated catalogues showing the wide range of shapes in which this material is offered by his firm. Some of the principal of these are crankshafts and axles, springs, forgings and stampings, gear-wheel blanks and the like. In the catalogue in question illustrations of the micro-structure of some types of the steel are given, as well as the particulars of a great number of tests, which should be of interest to the designer. The qualities of the vanadium steel produced are set forth in detail, in addition to which a large number of different parts are shown. This firm also manufactures high-quality carbon steels suitable for various purposes, including special steels for tube-drawing and for forging, the former being the result of long-continued experiments, and is said to be particularly adapted to the making of the highest grade of solid-drawn tubes. Forging steels of special quality, as well as high-grade nickel steels, constitute another line specialized by this firm. Copies of the pamphlet describing the entire range of steels produced by this mill may be had of the American agent.

### SOME BOOKS FOR AUTOMOBILISTS.

**Gas Engines and Producers; Marks-Wyer.** Under this title the American School of Correspondence, Chicago, has just issued a treatise on the modern development of the internal combustion motor and efficient methods of fuel economy and power production, the subject of Gas and Oil Engines being handled by Lionel S. Marks, S.B., M.M.E., and that of Gas-Producers by Samuel S. Wyer, M.E. The volume, of about 150 pages, really contains two independent treatises, about half being devoted to each, both subjects being copiously illustrated and detailing the latest achievements of modern practice where engines and producers are concerned.

**Balancing of Engines, Steam, Gas and Petrol,** is the title of a work by Archibald Sharp, just issued by Longmans & Company. With the exception of a few analytical investigations, the treatment of the subject is graphical and the work is intended both as a textbook for the student and a reference volume for the engineer. It forms a welcome addition to the works on the subject owing to the greatly increased amount of attention devoted to the subject of engine balancing as the result of the rapid development of the automobile motor. The only standard work on engine-balancing hitherto available is that by Professor Dalby (England), so that much of the subject matter of the new volume is published for the first time.

TENTH ANNUAL EXPOSITION AT THE GRAND PALAIS, WHICH HOUSED THE GREATEST NUMBER OF CARS EVER SEEN IN A EUROPEAN AUTOMOBILE SHOW.

## THE PARIS SALON IS GRANDER AND LARGER

PARIS, Nov. 21.—A few minutes before 10 o'clock on Tuesday morning, November 12, a Panhard limousine rolled out of the Faubourg Saint-Honoré entrance of the Elysée Palace, crossed the Champs-Élysées and pulled up in front of the main entrance of the Grand Palais as the neighboring clocks chimed ten. President Fallières and his military attachés stepped out, were met by the Minister of War, the Minister of Commerce, the heads of the Parliament, police and military forces of the capital, and mounted the broad staircase lined by tall, white-breached Republican Guards, while the strains of the "Marseillaise" rung out and all hats were doffed. At the head of the stairs Gustave Rives, Marquis de Dion, Baron de Zuylen and a host of constructors whose names are known the world over, stood hat in hand to receive the distinguished group. The usual words of greeting, and the tenth annual Paris Salon was inaugurated much as its immediate predecessors had been. But the presidential duties only terminated an hour and a half later, after all the principal stands had been visited rapidly and some speech-making done at each.

In its main lines the tenth salon is like that of last year; the ground floor of the Grand Palais is reserved exclusively for pleasure vehicles, the lower gallery is given over to complete cars and examples of bodywork, and on the extensive upper galleries, with their adjoining halls equal in floor space to the area of Madison Square, are shown motorcycles, bicycles, and the thousand and one accessories connected with automobiles.

### Temporary Buildings Erected for Commercial Vehicles.

Three hundred yards away, on the opposite side of the River Seine, a huge temporary building, equal in area to the Grand Palais, has been erected specially for commercial vehicles. Although interior decoration has not been neglected, there is more of the factory than the reception hall in this building, scores of power plants being in motion, for the production of electric light and a variety of industrial purposes, big gasoline and still larger gas engines furnishing the motive power; machine tool makers from Germany, America, France and England have machines at work cutting gears, grinding cylinders, and transforming more or less rough bars of steel into finished crank and camshafts. On the stands are omnibuses, trucks varying in size from the light rapid delivery vehicle to the formidable Renard train, gasoline cabs, a few steam tractors and still fewer electric trucks.

Motor boats have broken adrift from the main exhibition and are housed in the Palais Moderne, a short distance further out of town. Although the penalty of excommunication is declared to await any constructor who exhibits at a rival show, there are a sufficiency of firms interested only in the motor boat to form a fairly satisfactory independent nautical show.

### What Ten Years Have Brought Forth.

The present salon being the tenth in an unbroken line of succession, an effort has been made to give it even greater éclat and make it more of a national event than any of its predecessors. In 1898 Gustave Rives organized a sixteen-day show in the Tuileries Garden, uniting 340 firms and receiving 140,000 paying visitors. Two years later a move was made to the Grand Palais, the present being the eighth annual exhibition held there, each one under the control of the Automobile Club of France, and with Gustave Rives as manager. From 33,000 square yards of exhibition space last year the amount has been increased to 47,840 square yards by the construction of the hall on the Esplanade des Invalides, making this automobile show not only the largest in the world, but also the largest trade exhibition of any kind ever organized. The total number of exhibitors is 1,400, of which 1,100 are French and 300 foreign. Italy, Germany, and Belgium are represented by all their most prominent firms; Eng-

lish makers of automobiles are present to the number of four, and America has Ford as sole representative. In the machine tool section America is completely represented, all the makers from across the Atlantic being represented by agents. The estimated value of the exhibits, according to the declarations made for insurance purposes, is \$8,000,000, compared with \$6,000,000 last year. In 1906 there were 450,000 paid entries during the seventeen days of the salon; this year, owing to the decennial, it has been decided to remain open twenty days, half a million paid entries being expected. Actual attendance will be considerably larger, for on all but society days free passes are distributed.

### Illuminations Are on a Grand Scale.

External illuminations comprise not only the two exhibition halls, but all the surrounding avenues, from the Rond Point in the Avenue des Champs-Élysées to the extreme east of the Place de la Concorde, including the premises of the Automobile Club of France; from the Champs-Élysées to the temporary hall on the south side of the river is a magnificent luminous avenue, enhanced by the graceful decorations of the bridge itself. The Grand Palais being one of the most artistic buildings in the city, illuminations have been employed only to throw into relief its graceful outline and sculptures, all the lights being placed behind the columns or in the roof of the wide gallery, throwing a gentle white light on the inner portions and decorative friezes of the building, but developing the main lines more pronouncedly by reason of their sombreness. The temporary hall, on the other hand, is a mass of light, forming a termination to the luminous avenue passing in front of the Grand Palais and over the river.

The internal decorations are marvelously effective and artistic, the metal columns of the building and the metal work of the roof being picked out in bands of soft colors. Under the big central glass dome is the masterpiece of luminous decoration, a ball of light in the center, with colored bands radiating from it, and a background giving the effect of illuminated lace work. From each corner of the big hall electric searchlights shine upon the central portion, the ensemble being of such an effect as to altogether beggar description. The estimate of \$600 an hour for lighting the building and stands does not appear at all exaggerated, when one has seen the effect produced by the quarter of a million lamps. Although the full illuminating power is only turned on from 4 to 6 o'clock each day, it is estimated that the total cost of illuminations for the entire exhibition will be \$34,500. An unfortunate feature of the decorative scheme is that it has been the cause of loss of life, several workmen dropping from the dome with fatal results in one if not two cases.

### Lavishness of the Decorations.

Individual stands are on the same lavishness as the decorations of the hall, and although the design is left entirely to the firms concerned, there is not a single case of inartistic construction or anything which mars the beauty of the whole. Illuminated wrought ironwork stands predominate, last year's designs being employed in more than half the cases, with certain embellishments. De Dion is one of the few having entirely departed from last year's design with a model of the gate of the famous Winter Palace at Pekin, in commemoration of the journey of their cars from Pekin to Paris this summer. For the first time since a show was held in the Grand Palais there were one or two vacant places on the stands. Forty-eight hours before the official opening order was given that no more vehicles should be allowed to enter the Palais. Previous to this trucks had been entering by the north door, passing down the main alley, dropping off their loads where needed and leaving by the south door. After they were refused admission, one of the doors had to be built up, several pits filled, some of the pathways cemented and carpets laid.

MICHELIN EXHIBIT, WITH "BIBENDUM," THE TIRE MAN.

Late arrivals, therefore, will have to be carried to their respective stands by gangs of workmen during the night.

Opposite the main entrance, in the most conspicuous part of the building, is the stand of honor, decorated in blue satin and containing the Fiat victorious in the Grand Prix, the Darracq which won the Sporting Commission Cup, a Peugeot winner of the Coupe de la Presse, and a De Dion which took part in the Pekin-Paris run. At the commercial section there is an interesting retrospective exhibition of automobiles which attracts considerably more attention than the retrospective bicycle exhibition of last year, also organized by M. Baillif of the Touring Club of France. From the first road locomotive invented in 1770 by Cugnot, the development of the automobile is shown by such models as Léon Bollée's "Mancelle," De Dion steam tricycles, a 2 1-2-horsepower Panhard Levassor of 1892, the Peugeot which won Paris-Bordeaux and return in 1895, Thery's Brasier which won the Gordon Bennett Cup for France in 1904, and a modern machine by way of comparison.

#### Tendency Is Towards Six Cylinders.

Contrary to what is generally reported on the fixity of design, there are fully as many changes on 1908 European models as were to be observed for 1907 or 1906. Speaking generally, the tendency is towards six cylinders for the largest cars—the automobile de luxe—and towards the greater development of small popular vehicles. It cannot be denied that the six-cylinder engine has gained ground enormously, for whereas in 1905 there were only three types at the Paris Salon and 23 in 1906, there are this year 77 distinct six-cylinder models on exhibition, this number comprising only those firms building a complete car. Those having joined the ranks this year include such well-known firms as Renault, Panhard, Berliet, Delaunay-Belleville, Brasier, Gobron Brillie, and Mors. Panhard and Brasier both had a six model last year, but so far as can be learned it was more of an experiment than a commercial proposition, produced to meet the request of a few enthusiasts. Generally there is little enthusiasm shown for sixes, even among those now marketing them. Builders recognize their superiority in the matter of flexibility and absence of vibration, but they cannot sufficiently forget the disadvantage of a six-cylinder engine to recommend them unanimously to the public. Although everybody who is anybody is now producing sixes, nobody is building them in large quantities, and there is not a single house in France building sixes exclusively, as is the case with some English and American firms. Prices generally are maintained. On the largest models

there is a reduction in price, it is true, but the medium and lower-powered cars are marketed at the same price as last year, with a few exceptions where increase has been made.

Voitures are being given the attention they deserve, there being now on the market a score of excellent little single or two-cylinder cars selling at slightly less than \$1,000. There is the same pronounced tendency, too, for the big firms to produce moderate-priced touring cars—four-cylinder engine of about 16 horsepower, with high-tension magneto, selective transmission and shaft drive, selling complete with touring body for \$1,500. Luxuriousness in touring has reached a high stage, closed bodies having every comfort imaginable, and more cars than ever before being shown in which provision is made for protecting the driver from wind and rain, while remaining separate from the passengers.

#### Four-cylinder Castings in One Piece.

Four cylinder castings in one piece have gained a prominent position, such progress having been made in foundry methods that fours in one block are now produced with as much certainty as single cylinders were cast a few years ago. In the chassis intended for cab service and the numerous examples of town vehicles this method is especially advantageous, for it gives a smaller and more compact engine, diminishes weight, simplifies cooling and reduces the water pipe connections. The tendency towards a single casting is in line with the greater simplicity and accessibility of the leading makes. High-tension magneto as a source of electric supply is particularly pronounced. Two complete systems are not considered as necessary as formerly, and in only very rare exceptions—less than 1 per cent. of the whole—are storage batteries relied upon as the primary source of electric current.

Attention has been given to the transmission, which in a very large majority of cases is of the selective type, a strong tendency also being towards two direct drives, as on the Berliet. Brakes have been given close attention, a number of interesting examples being shown of methods of braking by the engine. In

AT NIGHT THE GRAND PALAIS PRESENTS A GORGEOUS SPECTACLE.

the matter of suspension three-quarter elliptic springs have strongly increased in favor for the more powerful cars, entirely driving before them the platform type. The transverse rear spring remains on the smaller models, where it gives good results without the prejudicial twisting movement noticeable on the large cars and especially those with chain drive. Multiple disk clutches are more in favor than ever, while final drive by side chains has gone out of fashion in equal proportion. Two of the latest and most important converts to shaft drive are Panhard and Dietrich. The Panhard case is especially noticeable, for though the pioneer firm has built small cars for years none of them have been fitted with live axle. A few years ago a couple of shaft-driven racers were produced, but the practice was not followed in touring cars. Both Dietrich and Panhard limit the shaft to their smaller models, equipping all the larger cars with side chains, as before.

More important than the tendency towards shaft drive is that towards the inclusion of the gearbox with the differential on the rear axle. The practice is not new, but it is not until this year that it has been at all prominent. There is a

SINGLE-CYLINDER, SIDE-CHAIN DRIVEN PEUGEOT LIGHT CAR.

driven off an extension of the camshaft. From the pump the air is carried to a reservoir within the frame, where it is stored at a pressure of 60 pounds to the square inch. By means of a bypass the air is admitted to the cylinders on pressing a lever; in the same way it can be employed for inflating tires. Some attention has been paid to the lubricator and the radiator has been so modified that to dismount it is now a very simple matter. It is reported that next season Renault will produce another large series of popular two-cylinder cabs of an improved type. In the industrial section the firm showed a 35-horsepower air-cooled eight-cylinder engine with the cylinders placed in V, said to be designed specially for aeronautical work.

By abandoning both chain drive and armored wood frame, Panhard has produced a chassis departing considerably from those of previous years. Three-quarter elliptic springs are employed on the new 15-horsepower model, the tops of the springs being attached to the frame by means of brackets. Single cylinder casting is retained, but several new features

are noticeable on the engine, most important being a sliding camshaft operating the exhaust valves, by means of which the engine can be used as a brake. The flywheel, instead of form-

THE ONLY FRICTION-DRIVEN CAR MADE IN FRANCE.

good example in the new Darracq with a solid axle carrying the road wheels, deeply bowed to allow the oblong gearbox containing the change-speed gears, differential and driving bevels to be bolted on it. The driving shafts pass through the bored ends of the solid axle and drive the road wheels through the medium of a clutch. Other features of the new Darracq are four cylinders in a single casting, with the intake and exhaust piping embodied in the casting; piping is thus simplified to such an extent that all that is necessary is a short straight pipe from the carbureter and a single pipe from the manifold to the muffler.

Renault has produced a new six-cylinder model of 50 horsepower, but has made but few changes in the four-cylinder models. A self-starter now forms part of the regular equipment; a device of this nature was shown last year, but does not appear to have been adopted on any other than the show model. This year's type is carried on the forward end of the engine, and consists of a small flanged air pumping cylinder, the piston of which is

NEW MODEL LIGHT DARRACQ WITH SINGLE PIECE CASTING.

INLET SIDE OF DELAUNAY-BELLEVILLE SIX-CYLINDER MODEL.

THE GOBRON-BRILLIE SIX MERELY MEANS AN ADDED UNIT.

ing part of the clutch, serves as a fan only, the ventilator behind the radiator being abandoned. The clutch is enclosed within a separate case behind the flywheel and immediately in front of the gearbox. The live axle is a particularly sturdy construction for a car of comparatively small power and should have none of the weaknesses sometimes attributed to this organ. On the larger chain-driven models a new self-starting device has been fitted, the arrangement consisting of an air pump working from the clutch shaft and compressing air into a tank from which it is admitted to the cylinders by means of a rotary valve.

An entirely new model has been produced by the Hotchkiss Company, designed specially for town use. The four cylinders are cast in one piece, with consequent simplification of piping and compactness of engine. A new carburetor has been produced, declared to give greater flexibility of the engine, and the now popular type of three-quarter elliptic springs has been adopted, other features being practically the same as on the firm's larger models of last year. Owing, it is declared, to the difficulty of obtaining ball bearings of uniformly good quality, the Hotchkiss Company has abandoned their use on the crankshaft of the new 20-horsepower town vehicle.

New six-cylinder cars have been produced by Delaunay-Belleville, the peculiarity of which is that the larger model, rated at 40 horsepower, has cylinders cast separately and a crankshaft with seven bearings. In the 15-horsepower six-cylinder model the cylinders are cast in two pairs of three, with valve chambers on one side and a single camshaft.

Prominent in the new Fiat model of six-cylinder engine is high-tension ignition by Simms-Bosch magneto in place of low tension. In this connection it is interesting to note that only six models of the seventy six-cylinder chassis at the show were fitted with low-tension magneto, among them being Brasier, Itala and Peugeot.

There are wide possibilities in the device to be found on the Berliet six for compressing air into a special tank at a pressure of 160 pounds, to be used in the cylinders whenever the motor has to be called upon to give extra power for a short period. The compression is done when the motor is running light, as when descending a hill, or when braking, and the compressed air can be communicated to the cylinders immediately on operating a small lever. There are several cases of gasoline electric cars for town service, having the advantage over those shown in previous years of a considerable saving in weight and size. One of the most interesting is the G. E. M., produced by a new company of which Girardot, formerly of the C. G. V. firm, is at the head. There appears to be a tendency towards the abolition of torque stays, utilizing instead a strong housing for the propeller shaft. There is an example of this in the new 12-16-horsepower four-cylinder Peugeot model. On this car also the side brakes are operated by the pedal and the brakes on the gearshaft by the side lever, thus relieving the bevels and differentials of many strains. To make the car suitable for drivers of different sizes, brake and clutch pedals are adjustable on the Peugeot.

For originality in suspension the Stabilia chassis is in a class by itself. The entire chassis is underslung, both forward and at the rear, the rear suspension being of the platform type with the transverse spring at the forward end and not in the rear; it thus hangs above the frame members but below the propeller shaft and the rather original torsion rod.

#### Increased Attention in Commercial Vehicles.

Commercial vehicles shown in the industrial section show remarkable progress over the exhibits of last year, being more numerous in every class and generally a better set of vehicles. The older firms, having made a name for themselves in the

THE HISPANO-SUIZA, A SPANISH SIX-CYLINDER PRODUCTION.

CARBURETOR AND MAGNETO SIDE OF THE NEW FIAT SIX.

pleasure automobile, are turning seriously to the commercial section, evidently realizing that whereas the field for high priced pleasure chassis is likely to become more restricted, the possibilities of automobiles for commercial purposes is practically boundless. Dietrich is one of those quite recently devoting a large amount of attention to the production of heavy trucks; Darracq has adequate representation in the Darracq-Serpellet combination; Panhard appears to be developing this class of business, and Renault is also paying some attention to motors for other than pleasure vehicles. The exhibition of this latter firm in the industrial section consists of a 10-horsepower cab, a 50-horsepower marine engine, a model of compactness, and the special eight-cylinder engine for flying machines. Panhard-Levassor has four distinct chassis for commercial vehicles, two of which are identical with their ordinary touring car chassis, and the other shaft drive with differential and gearbox on the rear axle. A 24-horsepower motor was also shown in motion with alcohol as fuel, linked up to a dynamo and arranged to show the power developed at all speeds and with varying fuel.

For the heaviest types of trucks there appears to be a tendency towards the use of six wheels, a solution of the heavy weight problem which has been before the public a long time but has never received full attention until now. Eugene Brillié has a vehicle of this type, as has also Dietrich, De Dion and Berliet.

MOTOR AND GENERATOR OF THE WESTINGHOUSE GASOLINE-ELECTRIC.

Effort is about equally divided towards the production of suburban 'buses carrying from six to thirty passengers, and the development of trucks and delivery vehicles. Trolley car services not being a very important feature in any part of Europe, there is a wide field open for reliable and economical 'bus services, similar to those at present in use in Normandy and other parts of France during the last two years. Gasoline omnibuses for city use also attract considerable attention, there being a big field for this class of vehicle in all the large cities of France, England and Germany. Steam does not find much favor here. One or two firms employ steamers for six to ten-ton trucks, but for all other purposes Darracq-Serpellet has the field practically to itself, from a mechanical standpoint, though in the business field pressed hard by the numerous powerful gasoline cars. Taximeter cabs, though certainly belonging to the commercial section, can be said to attach equally well to the pleasure field, for although the more important firms have designed special chassis for this work, as soon as they are found to be satisfactory they are adopted equally in the town pleasure carriages, the line of demarcation between the two sections being lost.

Standard lines of construction have been completely departed from in the Royal delivery vehicle, the peculiarity of which is that the entire motor group is carried slightly forward of the rear axle and transversely across the frame. It consists of a single-cylinder De Dion motor, a cone clutch, and selective transmission, drive being from the sprockets on the counter shaft to

OFF SIDE OF THE NEW DE DION FOUR-CYLINDER MODEL.

the rear road wheels. The power plant is exceedingly compact, one of the devices to save space being the cone spring within the hollowed shaft of the sliding gear shaft. With a wheel base of 96 inches, it has been possible to obtain a space of 71 inches for body between the axles, while leaving the power plant fully accessible. The driver's seat, which is raised to a considerable height, is at the rear of the chassis, but slightly ahead of the axle, the entire frame being suspended between the axles and not overhanging at either end. Below him, and on his left-hand side, is the engine, covered by a metal hood easily removable. Provision is made for easily removing the driver's seat, leaving the entire power plant as accessible as if it were on a shop bench. High-tension Bosch magneto is used on the engine, with fixed sparking point; engine speed can be varied from 500 to 1,500 revolutions a minute through variations of the exhaust lift by means of a foot pedal. Steering is through the front wheels, the connection being brought to the driver at the rear and operated by the usual inclined steering column and wheel.

It is perhaps only a small matter, but it is indicative of sound business policy, that automobile omnibuses should be employed very extensively in conveying visitors from all parts of the city to the show. By arrangements with the constructors a number of these vehicles have been placed at the disposition of practically all the newspapers and make journeys at regular intervals from the publishing offices or other central point to the Palais. The journeys are free for all and are appreciated by the public.

CARS PARKED OUTSIDE THE GRAND PALAIS DURING THE COURSE OF THE SHOW.

### EARLY PREPARATIONS FOR GRAND PRIX.

Rumors regarding next year's racing are plentiful in the salon, where all the most important drivers congregate, and where officials gather to talk over prospects for the coming season. According to the Fiat people, Nazzaro has already obtained the racer which he will drive in the Grand Prix of 1908 and is try-

DOUBLE AXLE CONSTRUCTION CHARACTERIZING THE DARRACQ.

ing it out on the road. Although of 155 millimeter bore, compared with 185 this year, the car is said to be even faster than the winner of the race on the Dieppe circuit. Last year fuel consumption was limited, while for the coming race there is no limit. It is not known what is the length of the stroke, though it is admitted that it is very long, there being no limit to the stroke under the new racing rules. Rumors that Lancia would not drive again are incorrect. The team will be Nazzaro, Lancia and Wagner.

For next year Renault has secured the services of Gustave Caillois, who designed the Thomas cars for the last Vanderbilt race, and will entrust him with one of the Grand Prix racers. His companions will be Szisz and Dimitrievitch, the latter little known to the public, but thoroughly experienced in international races, having been the mechanic of Szisz for several years.

Théry, after two years of comparative idleness, has been induced to enter the Brasier team again and next year will have

the leading car from the Trefle à Quatre factory, his companions being Baras and Bablot, both of whom drove in the 1907 race. Benz is building three cars, one to be driven by Hemery, the second probably by Hanriot and the third by a German. Mercedes will again race with Willy Poegé and Saizer as drivers, Jenatzy retiring in place of some one yet to be chosen. Henry Fournier announces three cars for Itala, one of them to be driven by Cagno. Pipe also declares that three racers are building.

The Mors firm, after abstaining from all races for several years, announces officially that next year it will return to the most important events with Gasté and Landon as drivers and one other yet to be chosen. Bayard-Clément has put all doubt at rest by a declaration that next year the firm will be ready with three cars for the Grand Prix. It is M. Adolphe Clément himself who has made the statement, with the additional information that the new racers are already under construction, so that it may be accepted as accurate. Other firms known to be busy on racing cars are Motobloc, Germain, Dietrich and Panhard.

Persistent rumors are abroad that the Dieppe circuit will again be the scene of the national race. No official decision has been arrived at and nothing definite will be known until about the middle of January, but it is so strongly felt that the Dieppe course is the only one on which the race can be a success that all are convinced the club will not search further.

## WELLMAN CONFIDENT OF FLYING TO THE POLE

**WELLMAN AND COMRADES'**  
Vaneman (on the left). Reisen-  
berg (on the right).

**U**NDETERRED by his failures of the past summer, and still optimistic of the possibilities of reaching the North Pole with the aid of a dirigible balloon, Walter Wellman has returned to this country, reaching here on the *Majestic* on Thursday last. Mr. Wellman was not of the opinion that the summer had been wasted by any means, as, in addition to having demonstrated what his airship, the *America*, can do, he has a well-established plant and ship ready for the renewal of the campaign next year or the year following, and will be able to dis-

pense with a great deal of preliminary work that would otherwise be necessary before undertaking the polar voyage.

Speaking of his trials of the airship itself, Mr. Wellman was confident that his basic plans were correct and that only slight modifications in the mechanism of the dirigible balloon would be necessary. "The *America* proved strong and stable and her speed was much greater than we had counted upon," he said. "We had very little opportunity for trials, as the summer in Spitzbergen this year was the stormiest and most unfavorable for an expedition like mine that has been experienced in many years.

The trial of September 2 was not a successful voyage in any sense of the word, but proved a successful test of the *America*. We had an opportunity to test our retarder as well as our guide rope of leather stuffed with food. Both proved efficient beyond our expectations. Granted the proper conditions, which means a southerly wind above all other things, we will no doubt have an opportunity to take advantage of these devices while over the pack ice and our chances of making a successful trip to the pole and back are more than good."

While sojourning in Spitzbergen, engrossed in the work of preparation for his trip, Mr. Wellman has found time to closely follow aeronautical developments in the interim, and was particularly enthusiastic over the possibilities of the balloon as a weapon of warfare. "It is gratifying to note that the American Government has at last come to a realization of the situation, as what has been accomplished in Europe plainly demonstrates that such an aerial ship could inflict millions of dollars' damage upon an enemy.

PELTERIE'S SEVEN-CYLINDER MOTOR, SHOWING CAM MECHANISM.

MOTOR AND PROPELLER FOR SANTOS-DUMONT'S FLYER.

### NEW AEROPLANE FOR SANTOS-DUMONT.

PARIS, Nov. 19.—Instead of being wholly engrossed in experiments on the water with a view to obtaining a speed of 60 miles an hour, Santos-Dumont has surprised the public by producing an entirely new aeroplane and getting it rapidly into commission preparatory to a trial for the Deutsch Archdeacon prize.

No. 19, which has already been dubbed "*The Butterfly*," because of a slight resemblance to that insect, is smaller and lighter than any of its predecessors and constructed on entirely new lines. The main chassis is formed of steel tubes, mounted on three rubber-tired wheels, two forward and one in the rear. The main bearing surface, as will be seen from the illustration, consists of a couple of lateral wings, 17 feet from tip to tip and 7 feet from front to rear. These two wings are covered with varnished silk, their framework being of bamboo. The steering and stability organs are a couple of vertical rudders placed slightly forward and to the left and right of the wings, a horizontal elevating rudder in front of the machine and a rear rudder mounted with a universal joint and capable of being turned in any direction. The total weight of the apparatus is 128 pounds.

One of the most interesting exhibits in the aeronautical section of the Paris Salon is the seven-cylinder motor designed by Robert Esnault-Pelterie for use on his own flying machine and now offered to the public. With a total weight of 108 pounds, it has been possible to obtain 35 horsepower under French rating. The cylinders, which are air-cooled, are attached to a circular crankcase, the two at each extremity forming a group, and the exhaust valves in the cylinder heads are operated by an ingenious circular series of cams.

### THE AERO CLUB OF NEW ENGLAND.

BOSTON, Nov. 25.—The Aero Club of New England, which was organized in a temporary way several years ago, and which has since lain dormant, was formally organized by the election of officers at a meeting held in this city last Thursday evening. The club also received a communication from the Massachusetts Automobile Club inviting it to make use of its clubhouse for meetings until it should have a clubhouse of its own. The announcement was also made of the offer of a silver trophy for a balloon competition, the finish of which shall be Boston Common. A. Lawrence Rotch, director of the Blue Hill Observatory, was elected president. The other officers are as follows:

Vice-presidents, Charles J. Glidden and Frank E. Stanley; secretary, Alfred R. Shrigley; treasurer, Harry G. Pollard; directors, President Rotch, Charles J. Glidden, Henry Howard, George E. McQuesten and T. E. Byrnes. The incorporators are thirty-seven in number.

### AERONAUTICAL CLUB FORMED IN CHICAGO.

CHICAGO, Nov. 25.—Incorporation papers for the Aeronautique Club of Chicago were taken out on Friday of last week. The new organization has the backing of several business men and will seek to promote the sport actively in this city. Contracts have been let by the club for the building of a \$1,500 balloon, and plans are under way for a series of races next spring, the first to be sailed on Memorial Day and the last July 4. A \$1,000 cup has been pledged to the club as a trophy. C. A. Coey is president of the club, Charles E. Gregory first vice-president, A. B. Perrigo secretary, and H. C. Foster treasurer.

"THE BUTTERFLY," NINETEENTH AEROPLANE CONSTRUCTED BY SANTOS-DUMONT SMALLER AND LIGHTER THAN PREDECESSORS.

BOX SPRINGS GRADE, RIVERSIDE, CALIFORNIA, WHERE THE ANNUAL THANKSGIVING DAY HILL CLIMB WILL BE HELD.

### SOUTHERN CALIFORNIA'S ANNUAL CLIMB.

LOS ANGELES, CAL., Nov. 22.—Southern California's annual Thanksgiving Day hill-climb over the Box Springs grade, Riverside, will be a bigger event this year than ever before. The list of entries exceeds all former records, and they are still coming in. The course has been put in first-class shape, and with a few of the sharper turns cut down the record of 4:53 for the three miles is certain to be lowered.

Riverside is sixty miles from Los Angeles, but a majority of the entries come from this city, the autoists running up the evening before. The road between the two cities is one of the most beautiful in the southland, and hundreds of machines line the course to see the cars make the climb. Last year the honors were won by a Tourist, Cadillac, Stevens-Duryea, and Maxwell.

The hill is such as only some of the far Western States can provide for such an event and to the cars of but a few years ago would have been next to impossible at anything that could be termed speed. With the experience of last year's climb fresh in mind, the course has been improved in a number of ways, promises being bright for the most successful event held in California.

### ORMOND-DAYTONA LAST WEEK IN MARCH.

The Florida East Coast Automobile Association, through its New York representative, W. J. Morgan, has made arrangements for co-operation with the Automobile Club of America in connection with the conduct of the annual Ormond-Daytona meet, which will probably take place the last week in March. The A. C. A. Contests Committee, of which Robert Lee Morrell is chairman, will make up the list of events, to include three principal races, one for strictly racing cars, another for stock cars, and a third for amateur drivers. The mile race for the Sir Thomas Dewar trophy will also take place, the entrants being confined to cars which will be required to qualify by going at least twenty miles at a minimum speed of 45 seconds to the mile. Mr. Morgan and a member of the A. C. A. committee will leave for Florida this week to complete final arrangements for the meet.

Mr. Morgan, who is the originator of the "Climb to the Clouds" up Mount Washington, announces a series of trials to take place in the White Mountains during the last week in June, the sixth day to be devoted to the eight-mile climb of Mount Washington.

## FUTURE EVENTS SCHEDULED ON THE AUTOMOBILE CALENDAR.

### AMERICAN.

#### Shows and Meetings.

- Nov. 30-Dec. 7.—Chicago, Coliseum and First Regt. Armory, Eighth Annual National Automobile Show, and First Annual Commercial Vehicle Show, National Association of Automobile Manufacturers.
- Dec. 9-14.....—Detroit, Riverview Park Auditorium, Detroit Automobile Dealers' Association. LeRoy Pelletier, manager.
- Dec. 14-21.....—St. Louis, Mo., Jai Alai Building, Second Annual Auto Show, St. Louis Automobile Manufacturers' and Dealers' Association. D. M. Strauss, manager.
- Dec. 28-Jan. 4.—New York City, Madison Square Garden, Importers' Salon. C. R. Mabley, manager.
- Jan. 14-18.....—Hartford, Conn., Foot Guard Hall, Hartford Automobile Dealers' Association.
- Feb. 1-8.....—Providence, State Armory, Automobile Show. Frank M. Prescott, manager.
- Feb. 10-15.....—Detroit, Light Guard Armory, Tri-State Automobile and Sporting Goods Association, Seventh Annual Show.
- Feb. 17-22.....—Cleveland, Central Armory, Annual Show, Cleveland Automobile Dealers' Association. George Collister, manager.
- Mar. 7-14.....—Boston, Mechanics' Building and Horticultural Hall, Boston Automobile Dealers' Association. Chester I. Campbell, manager, 5 Park Square.
- Mar. 9-14.....—Buffalo, Convention Hall, Sixth Annual Automobile Show, Automobile Club of Buffalo. Dal H. Lewis, manager.

- Mar. 21-28.....—Toronto, Canada, St. Lawrence Arena, Automobile Show. R. M. Jaffray, manager.
- Apr. 5-12.....—Montreal, Canada, Arena, Third Annual Automobile and Sportsman's Show. R. M. Jaffray, Mgr.

#### Motor Boat Shows.

- Dec. 7-14.....—New York City, Grand Central Palace, National Association of Engine and Boat Manufacturers. Chester I. Campbell, manager, 5 Park Square, Boston.
- Jan. 1-8.....—Chicago, Coliseum, National Association of Engine and Boat Manufacturers. Chester I. Campbell, manager, 5 Park Square, Boston.
- Jan. 25-Feb. 1.—Boston, Mechanics' Building, National Association of Engine and Boat Manufacturers. Chester I. Campbell, manager, 5 Park Square, Boston.
- Feb. 3-8.....—Buffalo, Convention Hall, First Annual Power Boat and Sportsman's Show, auspices of Buffalo Launch Club. Dal H. Lewis, manager.
- Feb. 20-Mar. 7.—New York City, Madison Square Garden, Fourteenth Annual Motor Boat and Sportsman's Show.

### FOREIGN.

#### Shows.

- Nov. 22-30.....—London, Agricultural Hall, Stanley Show.
- Dec. 5-22.....—Berlin, Germany, Automobile Show.
- Dec. 21-Jan. 2.—Brussels, Show, Palace of the Cinquantenaire.
- Jan. 18-Feb. 2, '08—Turin, Italy, Fifth International Automobile Exhibition, Palace of Fine Arts, Valentino Park, Automobile Club of Turin.
- Mar. 21-28.....—London, Agricultural Hall, Cordingley's Show.

## HOW CANADIAN AUTOISTS ARE ENCOURAGING ROADMAKING

TORONTO, ONT., Nov. 25.—A prize of \$500 has been awarded by the board of directors of the Ontario Motor League to the township of Etobicoke for the improvement made on a mile of the Lake Shore road extending west from the Humber river to Mimico creek. Another prize of \$100 was awarded to the township of Markham for improvement made on a mile of the main road running north from the village of Markham. Further prizes of \$50 and \$25 respectively were awarded to the supervisors in charge of the work on these roads.

The awards were made on the recommendation of A. W. Campbell, Ontario good roads commissioner, and the chairman of the committee of judges for the good roads competition, which was inaugurated by the Ontario Motor League last spring, and the funds for which were subscribed by Toronto members of the League. The other judges were William Dobie, of Toronto, on behalf of the League, and William Pugsley, representing the county of York.

In an exhaustive report to the League, Mr. Campbell commended very highly the work that had been done by the Etobicoke township on the Lake Shore road. It is understood that the total sum of \$4,000 was expended. The improvement included the laying of a foundation twelve feet in width throughout the length of the road, consisting of eight inches of flat rock over which another foot of broken stone was laid, and the whole covered and rolled with road rollers.

In all, eleven miles of road were entered in the competition by six municipalities. While all of these were not finished in time, the directors are well satisfied with the results of the competition. One of the sections entered was Dundas street.

The section of the road which earned the first prize was the worst piece of road between Toronto and Hamilton. The directors consider that the stimulus given to Etobicoke township has been an important step in securing a good road along the Lake Shore to Hamilton and the Falls.

In the course of his report Mr. Campbell comments as follows: "In the opinion of your committee, the competition has done much to awaken a more intelligent interest in the matter of road-making and road-expenditure. In nearly every section where entries were made keen interest was manifested and much attention directed to the subject, which will be of lasting benefit. During the carrying out of the work the fundamental principles of road-making, heretofore largely lost sight of, were closely observed and their benefits appreciated. Implements were used in forming the roads, preparing the material and applying it to the work which have been read about but not used by rural municipalities. The necessity for such implements and the importance of observing the principles laid down in the rules of your competition have been so forcibly impressed upon those in charge of the work as to have formed a text-book for their guidance, and have so impressed these axioms upon them that we have no hesitation in saying that as object lessons to guide the work of the future in these localities a valuable service has been performed.

"Good roads are largely a question of cost. The greater the expenditure the more rapidly can the highways be improved. By adopting the best and more efficient methods the cost can be reduced. Proper principles of construction, the preparation of suitable materials and the knowledge of the quantity required and its proper application to the road surface, and the formulating of the system for the care, protection and maintenance of roads, once properly made, form the text which your committee feel should be urged upon the attention of all those in charge of our road management."

The only other highway outlet from Toronto in need of improvement is the Kingston road, and it is probable that the Ontario Motor League will take steps next year to have the Norway hill, which has been in a very bad state for a number of years, put in good condition.

## PROMISING CONDITION OF AUTO INDUSTRY IN CANADA

TORONTO, ONT., Nov. 25.—Present conditions in the automobile trade in Canada seem to indicate a favorable amount of business for the coming year, considerable in excess of that done during the past year. All of the cars represented in Canada this year, most of them American makes, will be represented next year, while there are a number of additions to the field. New manufacturers are also springing up.

One of the most notable additions to the automobile manufacturers in Canada is the McLaughlin Carriage Company, the largest carriage concern in Canada, which has been in business for upwards of fifty years. This concern is capitalized at \$1,500,000, and has just completed arrangements to manufacture an American make of cars in Canada. The company began experimenting in the automobile business a couple of years ago, the intention at first being to produce a new type of car. Large additions to the plant have already been erected and the necessary machinery installed.

The Canada Cycle & Motor Company, manufacturers of the Russell car, are turning out 400 cars for the coming season. The Russell is well known in Canada and has an established sale. It is purely a Canadian car and has been on the market some years.

The Chatham Motor Co., of Chatham, which began business this year, state that they will produce 125 cars next year. The Chatham is also a Canadian type of car.

The Comet Motor Company will next year considerably increase its output. The company makes a car of European de-

sign called the Comet. This car ranks with the high-class cars made in Europe and retails in this country at \$5,000.

The Ford Motor Co. of Canada, Walkerville, Ont., is specializing on the Ford four-cylinder runabout, which it will produce in considerable quantities. This company has opened a selling branch in Toronto, where they have a garage 60x120 feet.

The Olds Motor Works of Canada has moved its sales headquarters, in charge of Frederick Sager, to Toronto, where it occupies large new quarters.

A new manufacturers' concern just incorporated is the Toronto Automobile Co., which intends to build a plant at Port Arthur. It is capitalized at \$100,000.

Among dealers the Dominion Automobile Company, of Toronto, Montreal and Winnipeg, will specialize on the Packard, Maxwell, Stevens-Duryea lines. The Automobile & Supply Company will handle, among other lines, the Pierce, Stoddard-Dayton, and Royal cars. Hyslop Bros., who have erected a new garage, will continue to handle the Darracq and the Cadillac. The Standard Automobile Company is a new concern which will handle the Peerless and Chatham cars.

In Montreal the Eastern Automobile Company will handle the same lines as the Dominion Automobile Company in Toronto. W. P. Kearney will sell Darracq and Olds cars. The Wilson Automobile Co. will sell Pierce, Franklin, Buick and Humber cars, and the Automobile & Import Co. the Reo. Other agencies are now being arranged for the coming year.

READY FOR THE OPERA, WITH COAT OF WHITE CONEY.

HAPPILY automobile fashions for cold weather have reached saner proportions than autumn styles boasted. All the superfluous furbishings that a short time ago were high in vogue have disappeared from garments designed for the woman of discriminating taste. Such details as were found a hindrance rather than comfort have been eliminated, and apparel for use in the automobile has assumed practical styles in general. Fashion autocrats are directing more attention to lines than to ornamentation; as a result the fur or leather garment that once was heavy and awkward is now transformed into a fashionable outer wrap; so perfect in style and finish that it may be worn on almost any functionary occasion where such demands are made. Furs, leather, and cloths of lighter weight but of no less warmth have supplanted heavy materials that made the motor coat a clumsy burden.

The well dressed woman who rides in an automobile chooses her apparel for the pleasure with as much care as she exercises over her handsomest evening raiment. She never loses sight of the fact that she must be warmly as well as becomingly clad. And with the great diversity of fascinating styles at her disposal she may own an outfit becoming to her particular style, and not depart so very far from what her personal fancy dictates. Capricious styles in coats and head coverings are many and varied. And one may wear just about what she prefers so long as she keeps within certain bounds of conventionality. On the other hand, if one desires extreme simplicity in the matter of dress there is also a wide range of attractive styles from which to make choice.

#### Furs of Every Description for Automobiling.

Furs of almost every description are now being employed in the making of automobile wear. Of the new pelts initiated for the purpose during the past year, Russian pony is perhaps highest in favor. A successful process in treating the skin renders it soft and glossy, resembling, as it does, broad-tail or baby lamb. When finest selected skins are used the appearance is so deceptive that often the garment is admired under the name of baby lamb, the observer not appreciating

the difference even at close range. The accompanying illustrations include a long coat of choice skins of which only the small moiré markings are used. The luxurious black lynx shawl collar and sleeve garnishments add much to the attractiveness of this sumptuous garment. Fancy metal buttons decorate the double-breasted front. A full satin lining finishes the inside.

Very stunning is the natural seal coat, with Gibson effect shoulders and picturesque hood lined with soft gray leather, which same material again appears on the sleeves. The hood may or may not be used, but for stormy weather it makes a capital head covering, protecting the face, as shown in the reproduction. The same style coat may also be had in sable marmot at lower cost than this superb garment commands. Going from one extreme to the other in the realm of fur coats, let me inform my readers that there is a splendid example of what can be done with inexpensive furs in a full length coat of wombat, and, cheaper still, is a black dog skin coat. These garments receive the same amount of workmanship in the cut and finish as do those many times exceeding their cost. A very comfortable one may be had as low as \$35.

#### Leather Has Lost None of Its Prestige.

Leather has lost none of its former prestige. Many of the season's smartest coats are fashioned of Scandinavian leather lined with light weight fur of one kind or another. If there is any preference given to color it extends towards olive green, although one sees leather coats in nearly all the fashionable dark tones. The Empire back is liked for this particular garment, the probable reason being that the weight then swings from the lower part of the yoke or baby waist, and not from the shoulders, as is the case in wraps cut on long, unbroken lines. The photograph pictorially describes the style referred to. This particular model is lined with marmot. Other leather coats in tan, red, gray, black, and blue-gray are attractively lined with genetie, which reduces the cost somewhat.

Automobile coats in cloth present many models for purchasers to select from continually, as this class garment is in demand the year through. Of these a number of stunning coats have appeared in two-inch block checks of tan and brown. Running down the back is a bias seam, the shoulders well fitted and flaring, and from a few inches below the shoulder line is an outward spring, which affords ample roominess below the waist-line, continuing to the bottom of the hem. Stitching is the simple finish on the edges of the two-inch strap of cloth that covers the back seam. Tailor stitching also finishes the sleeves, and often the two open fronts. From six to nine buttons, according to size, are required for the front fastening, and these are either of metal or leather covered. Any light weight fur may be employed for,

NATURAL SEAL, WITH HOOD  
Courtesy Scandinavian Fur & Leather Company

RUSSIAN PONY, BLACK LYNX TRIMMINGS.

turned back into two small triangles finished with a cloth button on the extreme points of each. A wide turn-down collar of green cloth lined with satin finishes the high neck where it closes with a stitched tab. Two-sided cloths of unusual thickness enter largely into the making of simple automobile coats. They come in a large variety of charming color combinations. One of the favored is in tan with a green stripe about three inches apart. Fur collar and cuffs

SCANDINAVIAN LEATHER, FUR LINED.

lining, but the same color scheme must be faithfully carried out to keep the tout ensemble intact.

On a wonderfully stylish coat of blue and green plaid cloth the seams are finished with a strip of green broadcloth stitched twice on the edges and ending in points covered with crow's feet embroidered with heavy silk. A single box plait laid in the middle of the back and stitched on the sides gives a swagger finish to the bias cut. From the upper side seams spring two circular sleeves or deep caps lined with green satin corresponding with the green inner lining of the coat. The corners, both back and front, of this cape-like sleeve are

complete cloth garments of this character, raccoon being much used. One of the most recent creations introduced by representative makers of smart apparel for motoring is a fifty-four inch white Coney coat lined with white satin and ornamented down the double breasted fronts with fancy metal buttons. Such a garment may be worn to the opera or any other functionary gathering, and is one of the most sensible investments found in dressy wraps for every occasion. Accompanying this simple but elegant coat is a voluminous head covering made of chiffon and mousseline and having the attributes of the most exaggerated French hood, so far as be-

comingness is concerned. Besides it is wonderfully comfortable in extremely cold weather. The same model is made with fur lining, which will render it sufficient protection in severest weather. Long leather boots lined with genetie or muskrat cover the evening slipper and close with patent clasps, making them easy of access and most comfortable over sheer silk hose and low-cut shoes.

Accessories of all kinds were never more varied. The average woman considers her hat, veil, gloves, and bag as much a part of her outfit as she does her coat. To own the most attractive details in dress for the use, one must examine all the new accessories that are brought out from time to time, and there are many. If you would save much time, it is advisable to patronize a reputable importer and manufacturer, where you may have your clothing matched up with the small fixings he will show you. There are numerous small dealers who fancy there are endless amounts to be realized in automobile apparel, and he will offer you all sorts of ridiculous articles, telling you at the same time they are imported from foreign marts, when in truth he has been sitting up nights trying to perfect something different. Very ridiculous are many so-called novelties that he exhibits. Any number of milliners have brought out absurd styles in headwear for which they ask enormous prices, and once you wear them you find their service lacking in almost every necessary essential for which they are intended.

If you do not feel that you care to purchase a handsome fur coat or leather dress, you can ride in bitterest weather in your street costume and furs with a chamois skin jacket under your coat and a leather bag lined with fur covering your limbs and hips. The particular bag that seems to meet all requirements is of black Scandinavian leather lined with opossum. This style opens at the side and may be released by pulling the clasps.

Hats vary in style and price, just the same as picture hats do. One may admire a blended muskrat cap with coquettish little brim and find it vastly becoming, while, on the other hand, one might see a sealskin hat of more attractive lines and find it impossible for the desired use. A shape with slightly full crown and visor front and back in blended muskrat is only \$10, while the same style in seal is \$35.

A vastly becoming little creation from Paris is in golden brown pony skin, and is featured among the newest innovations on account of the detachable hood that accompanies it. The model is fashioned after the shape of a close-fitting toque that may or may not be trimmed with aigrettes or quills or even velvet rosettes. When a touch of contrasting color is desired a bright wing adds just enough life to the soft brown fur to make it attractive.

Many persons suffer from dust and cold air penetrating the throat and lungs through the mouth. To overcome this unpleasant feature of automobiling there is a clever little silver wire screen mounted on an oval frame and attached to elastic cords which hold the protector in place. The illustration will give an idea of the position the mouthpiece takes when adjusted. Another innovation recently brought to light is the mica window with wire attachments for clasping to the hat or cap.

SILVER WIRE SHIELD FOR LIPS.

## LETTERS INTERESTING AND INSTRUCTIVE

### DID FREEZING CAUSE THIS JACKET LEAK?

Editor THE AUTOMOBILE:

[982.]—Our first freeze of the winter caught me with my radiator and all pipes full of water. The result, a cracked cylinder. I have examined it, and find that the crack is in the outer jacket only, and does not affect the compression. It, therefore, allows the water to spurt out, and I cannot use the car. I have a two-cylinder car, and the crack is near the end of the cylinder at the valve. Now, is there a fireproof cement that I could use to stop up the crack and make it water-tight? I might cover it with a metal paste were it not for the curved surface, which would make it pretty hard to completely cover. Kindly enlighten me. I have made the statement above that freezing is responsible for the crack. It may be that I am mistaken in this. My car was stuck fast for three days after the hard freeze, and it was impossible for me to turn the engine over. Finally it thawed out and I then drained all the water out and started the engine, and it ran for a very few minutes, not long enough for it to heat. Satisfied with things, and without making a thorough investigation, I left the car for the day, returning the next day and filling the radiator, cranked her up, and got a shower bath. Did the freeze crack the cylinder, or did my starting it up and causing the explosion in the chilled cylinder cause the crack? I don't believe this caused it, or it would have cracked the cylinder through and through, would it not?

Ft. Smith, Ark.

IGNORANCE.

There appears to be little doubt but that the freezing was responsible for the cracked water jacket, the difficulty in turning the engine over probably being due to the fact that the lubricating oil bound it at the low temperature. It is a peculiarity of breaks in wrought iron pipes caused by freezing that they do not always make themselves visible the moment water is sent through the pipe, so that a superficial examination would fail to reveal them; in fact, we have seen a case where the pipe stood a pressure of 10 to 15 pounds for almost half an hour before giving way, though when it did, the pipe opened more than 1-16 inch for fully three feet. This may be true of castings also.

Take a file and clean the metal round the break for 1-4 inch or so, and then apply a paste composed of one part sal ammoniac in powdered form; two parts flowers of sulphur, also powdered, and eight parts of fine iron filings. Mix with water into a paste thin enough to work into the crack easily, but still with sufficient body to stay where placed. This paste should be worked into the opening very thoroughly, and if it be possible to reach it from the inside so much the better; after filling the break, spread the paste over the cleaned outer surface about 1-8 inch thick. As this depends for its efficacy on rust binding the mass of filings and the broken surfaces, it must be allowed to stand for two or three days before using.

### REGARDING SECONDARY CONNECTIONS.

Editor THE AUTOMOBILE:

[983.]—Being a subscriber of "The Automobile," I take the liberty of asking you the following questions: There being two terminals to every secondary winding of a spark coil, one leads to plug and what becomes of the other? Is it grounded on the primary circuit? If not a trade secret, what is the composition of the friction surfaces of such cars as the Cartercar and Lambert? Is there a car made that has friction transmission with direct (no friction) shaft drive on high speed?

Kalamazoo, Mich.

W. C. BALL.

One side of the primary and one side of the secondary of all high-tension wiring systems as employed on the automobile are grounded, or, to put it in another way, have a ground return in order to save wiring. To simplify the coil connections the secondary and primary are often connected, making a common ground wire for both.

We believe such cars as you mention employ an aluminum facing on the stationary friction disk and a special paper composition on the sliding friction wheel. The latter is probably a trade secret. The Gearless car, which employs what is virtually a friction planetary gear, has a direct drive on the high speed.

### WHAT IS WRONG WITH THIS WIRING PLAN?

Editor THE AUTOMOBILE:

[984.]—I have a two-cylinder car. I have just bought a new coil (Pittsfield) for it. I enclose a diagram of the way I have wired it; have I got it right? I have only one battery wire running back to the coil. The other one goes to the transmission gear box for a ground wire, two wires to the plugs, and two to the timer, and it doesn't seem to work just right. Can you let me know through "The Automobile" if I am right? If I am wrong, could you give a small diagram in "The Automobile" of the correct way?

New York.

C. W. B.

You do not state whether you have made a ground connection from the coil or not, as one side of both the primaries and secondaries of both coils should be grounded to form a return path for the current. This ground connection is usually combined in one wire, the necessary interconnections being made on the interior of the coil box by the makers. Otherwise your diagram is correct, on which account we have hardly thought it necessary to reproduce it here. However, we think you could find a better ground connection for the battery than the gear-set housing; we should take this wire to some point on the frame or motor as near the timer as possible, as poor ground connections are often responsible for much ignition trouble.

### DIMENSIONS FOR A FOUR-CYLINDER MOTOR.

Editor THE AUTOMOBILE:

[985.]—I am going to build a new engine for my car and would like to learn through the columns of your paper if I am on the right track before going ahead. I have taken your paper, and I think it is the best automobile paper that I have ever read. If there is anything wrong with the measurements given below, I would be very much pleased to have you correct them.

Four-cylinder, 4 x 4 inches.

Connecting rod, 8 inches.

Valves.—Exhaust, 1 5-16 inch. Intake, 1 1-4 inch. Lift, 5-16 inch.

Crankshaft, 1 3-8 inch. Two-inch bearing between each cylinder and 4-inch bearings at ends.

Piston, 5 inches long. Three rings 5-16-inch wide. Wrist-pin set 2 27-32 inches from top of piston.

Copper water jackets. What should the water space be around the cylinder? Would 1-inch space over top of cylinder and around valves be too much? What should the thickness of the cylinder wall be? What should the volume of the compression be? What should the weight and diameter of the flywheel be?

Woodstock, Ill.

A READER.

We think the design of your motor could be considerably improved by making the valves both 1 1-2 inches in diameter, and 1 5-8 would be better, with a corresponding decrease in the lift, which could be reduced to 7-32, or at most 1-4 inch. We should increase the crankshaft to 1 1-2 inches, and here again a still further increase to 1 5-8 inches for this essential would provide a much higher factor of safety and make a better motor. The bearings are also too small; we should use a 5-inch bearing at the flywheel end, with a 3 1-2-inch bearing at the opposite end and 3-inch intermediate bearings. We hardly think the dimensions you give for these would prove at all satisfactory in practice, as is evident from the liberal bearing dimensions given by a number of prominent motor builders. With a copper water-jacket less water would be required than with the usual cast-iron integral jacket and a 5-16-inch space should be sufficient, with a 3-4-inch space about the valves and over the head. One inch would doubtless prove excessive for this, assuming, of course, a normally efficient circulating system. The cylinder walls should be 5-16 inch and doubtless the average foundryman would not care to undertake to make them any thinner than this and guarantee the result. Making the compression space 30 per cent. of the total volume displaced by the piston would be approximating standard practice in this respect. A 16-inch flywheel, weighing 100 pounds, the greater proportion of this weight being in the rim, would give a very steady running engine; if

necessary to give greater clearance or for other reasons, the diameter could be reduced somewhat, keeping the weight the same. None of these dimensions is arbitrary or absolute and doubtless nine out of ten designers would modify them in some way or other, but the uniformly excellent results obtained from standard motors of the foregoing proportions, as well as from dozens of others which differ in various ways, shows that success in motor building is not merely a matter of following hard and fast rules.

**AN ACCIDENT THAT WAS UNAVOIDABLE.**

Editor THE AUTOMOBILE:

[986.]—I am enclosing you a rough diagram of what well may be termed an "unavoidable accident" that I witnessed on Broadway this morning. An untoward combination of circumstances made all ordinary precautions on the part of the drivers useless. The inci-

DIAGRAM SHOWING SITUATION OF CARS THAT COLLIDED.

dent is of interest as illustrating the multitudinous dangers of city traffic. When first observed, A was running south on Broadway alongside the street car indicated, also proceeding in the same direction. At that time B was half a block or more east on Sixty-second street, coming toward Broadway. An excavation in the center of the street is indicated by the irregularly shaped, shaded portion. The driver of A could not see anything issuing from Sixty-second street as the parallel-moving street car obscured his vision in that direction for an entire block. B could not see A for the same reason. Just as B reached the crossing, the street car came to a sudden stop and B, seeing his opportunity, passed in front of it, only to collide with A. The damage was confined to smashed lamps owing to the low speed at which both cars were traveling, and B was the one that suffered.

A. L. WESTGARD.

New York City.

**WHAT ONE AUTOIST WANTS TO HAVE PRINTED.**

Editor THE AUTOMOBILE:

[987.]—I want to thank you for your "1,000 Miles of New England," published November 7, in "The Automobile." It is this kind of articles that appeal to the practical autoist. I have taken for four years eight different automobile publications, and, if my memory serves me right, this is the second or third American article published. We have had trips through Italy, touring through France, autoing in England, etc., etc., finely illustrated and descriptive in character. We are told how to build cars, and the science of automobile construction has been detailed ad nauseam. Every automobile race and hill-climbing contest has been given in detail, but nothing practical for the everyday motorist. We live in foreign lands and all of our manufacturers are trying to see how near they can copy foreign cars. But the American spirit lies dormant.

Do not our publishers and manufacturers realize that some of our craft are "stay at homes" and are pining for domestic food? Less than 5 per cent. of autoists go abroad with their cars for summer vacations, and so are little interested in foreign auto trips. But we would like to know of and see in some of our auto publications illustrated articles, descriptive of routes, grades, and road conditions in such places as, viz.: To and from the White

Mountains by different routes; through the Catskills by different routes; through the Berkshires, by the several routes; Hudson river district; Connecticut Valley from Springfield to the Canadian line; and the forty other scenic routes. But up to date no publication or guide book gives the slightest clue, only thus saith the book: "From Smith's to Brown's, 41-2 miles, take left fork at Meeting house and follow telegraph poles," etc., etc., but nothing of road conditions or grades. I followed one guide book descriptive of route, and while no mention of a hill was made, I found one one-half mile long with a grade from 12 to 18 per cent.

Now, what the practical autoist wants are illustrated articles telling him how and where to go. If to the Berkshires, how to start out; there are four ways, and all somewhat bad, one or two very bad, the worst, perhaps, over "Jacob's Ladder," where a farmer does or did do a thriving summer business pulling stalled cars up the hill. And yet, never to my knowledge, has any publication described it in any way or done anything to enlighten the autoist of the difficulty in negotiating it. The same is true of Crawford Notch, one entrance to the White Mountains, or Profile Hill, one outlet. There are lots of snares and pitfalls in the route of the autoist not warned against—hence articles like that just published by you are so welcome. Let's have more of the same.

Meriden, Conn.

GEORGE A. FAY.

**WHY SWINEHART TIRE PRICES ARE REDUCED.**

Editor THE AUTOMOBILE:

[988.]—It may be of interest to your readers to know that crude rubber to-day is selling at 35 cents per pound less than one year ago to-day. This is the lowest price which rubber has been sold at since November and December, 1903. The reduction in the price of crude rubber (we speak only of the best grades of Up-river fine Para) will undoubtedly cause a reduction of price of automobile tires and all other rubber goods in which large quantities of fine Para are used in their manufacture.

Owing to this reduction, the Swinehart Clincher Tire & Rubber Company has already announced a reduction in the price of its tires, to take immediate effect.

THE SWINEHART CLINCHER TIRE & RUBBER CO.

Akron, Ohio.

B. C. Swinehart, Vice-President.

**WIDE-TREAD CARS FOR SOUTHERN ROADS.**

Editor THE AUTOMOBILE:

[989.]—Answering the inquiry of T. A. Ansley, regarding runabouts for Florida roads we would say that the Premier Company has built cars with wide tread for Southern roads for the past three years. If the gentleman inquiring will call on, or address, the Owen Typewriter Company, Tampa, Fla., he will be able to get more information regarding a car such as he desires.

Indianapolis, Ind.

PREMIER MOTOR MFG. CO.

**LAMP TROUBLES DUE TO DEFECTIVE PIPING.**

Editor THE AUTOMOBILE:

[990.]—It is our practice to fully investigate thoroughly every complaint that comes to us, and in the past several years fully half of the gas lamp troubles are traced to defective piping. We are giving you herewith, for the benefit of your readers, a diagram of a correct system of piping, and it would pay all users of gas lamps to install the connections in this manner.

CORRECT SYSTEM OF PIPING FROM GENERATOR TO LAMPS.

Note that all pipes pitch down to drip cock. Pipes to each lamp should be independent, coming together at trap. Gas from generator, or tank, should enter trap below piping to lamps. Open drip cock at least once a week. Any repair shop can make and install the above, care being taken to fasten pipes securely so that there will be no chafing.

Amesbury, Mass.

GRAY & DAVIS.

## THE BALTIMORE SHOW WAS MOST SUCCESSFUL

BALTIMORE, Md., Nov. 25.—Despite the gloomy weather and the financial stringency, the third annual automobile show, which closed last Saturday night in this city, was the most successful of the three. The class of people who attended were just the class the trade was desirous of coming in contact with, and many sales were reported by the local dealers. Several New York and Philadelphia capitalists were so encouraged with what they saw at the local show that they intend to do business in this town during the coming year. Many new agencies have also been secured. R. F. Kaehler and A. M. Eastwick, of Philadelphia, have formed a partnership to handle the Ford car in this city. The firm will be called the Ford Automobile Company, and has a capital of \$25,000. Mr. Kaehler believes that with a little hustling over \$200,000 worth of business can be done.

The Mar-Del Company has taken the local agency for the Buick. The Lambert Automobile Company has taken the agency for the Maxwell cars, and the Rice Auto Company has secured the representation for the Crawford line.

Among the out-of-town visitors were William H. Kirkpatrick, sales manager of the Peerless Motor Car Company; William T. Saylor, district sales manager for the Olds Motor Works; H. M. Cole, sales manager of the Autocar Company, of Philadelphia, and J. E. Duff and J. A. Lutz, of Washington, who arrived in the Oldsmobile roadster that made the 1,100 non-stop run in Washington, and which has traveled over 14,000 miles.

Owing to the fact that the door leading to the tea room of the Hotel Belvedere was too small to admit the Matheson chassis, the exhibit was taken to the show building and was the center of attraction. It was called the model for 1912. The Matheson Company has established an agency for their car at 1002 Morton street, and has secured the services of J. J. Mason.

The success of the show was something of an argument for the holding of shows early in the winter, and against those who contend for a later date. It has been decided to regulate the shows in this city by the dates selected for New York, Philadelphia and Chicago.

### ECONOMY OF GASOLINE COMMERCIAL VEHICLES.

Demonstrations of commercial vehicles are far different things from the trials of the same name that pass current when the sale of a pleasure car is in question. The business man wants to be shown in no uncertain manner, and a good instance of how this is done is to be found in a recent four-day test made for Gimbel Brothers, a Milwaukee department store, by the Commercial Auto Company, representing the makers of the Logan trucks—the Logan Construction Company, Chillicothe, O., in Wisconsin. The tabulated results of the tests are given below and the table speaks for itself better than any description of the trials possibly could. As will be noted from this, nearly 1,000 packages were delivered in less than twenty-one hours' actual running time, with a consumption of 20 gallons of gasoline and 7 1-2 pints of lubricating oil. The car displaced three to four wagons with their corresponding drivers and helpers. The table follows:

Date	Routes	Wagons Dis- placed	Stops	Time	Gasoline	Oil
10/23 A.M.	East, Erie to North	3	100	1 hr., 20 m.	3 gal.	1 1/2 pt.
P.M.	East, Brady to City Limit	2	110	1 hr., 40 m.		
10/24 A.M.	South Side, inc. Bay View.	3	80	2 hr., 30 m.	3 1/2 gal.	2 pt.
P.M.		3	75	1 hr., 15 m.		
10/25 A.M.	West Side to City Limit..	4	160	2 hr., 30 m.	4 1/2 gal.	2 pt.
P.M.		4	186	2 hr., 15 m.		
10/26 A.M.	North Side to City Limit.	4	150	4 hr., 45 m.	9 gal.	2 pt.
P.M.		4	120	4 hr., 30 m.		
		27	981	20 hr., 45 m.	20 gal.	7 1/2 pt.

### NOW THREATEN TACKS AND GLASS.

ROCKVILLE, Md., Nov. 25.—Angered at the decision of Judge Henderson in the now celebrated Conduit road case, the farmers of the Potomac and Bethesda districts have made threats against the successful automobilists to the effect that they will

resort to scattering tacks and broken glass and stretch wires across the Conduit road, if it should become necessary, in order to prevent automobiles from running at dangerous speed thereon.

Marshall Collins, of Glen Echo, who had such a fine time in collecting money from the automobile owners, stated that since the case had been pending the autoists have been speeding at pleasure through Glen Echo, and that he has been recording their numbers. Now he threatens that, should an appeal be taken, and they win their case, he will haul the past offenders before his court and compel them to pay heavy fines.

### ONCE MORE THE STATUS OF THE AUTO.

BOSTON, Nov. 25.—The town of Ayer in this State has appealed to the full bench of the Supreme Court for a decision which involves the question whether automobiles have the same rights on the highways as horse-drawn vehicles. The question came before the court on an appeal from a decision against the town in a suit brought by William C. Doherty, an automobile owner who was awarded a verdict in the lower court for injuries to his automobile, which sank ten inches into the sand on one of the town's roads and became stuck. Work was being done on the road at the time and the accident happened at night.

The town claims that it is not liable to a traveler in an automobile, as the highway statute, which provides for liability, only makes it necessary that a town keep its roads in a safe condition for travelers with horses, teams and carriages. The town further contends that the Legislature did not intend that municipalities should keep their roads up to the smooth condition required by automobiles. Doherty claims that an automobile traveler comes within the statute, and that the town is liable at any rate because of the defective condition of the highway.

## EXPERIMENTING WITH ROAD BUILDING MATERIALS

YORK, Pa., Nov. 25.—With a view to securing the very best limestone for the State highways—which means so much of an improvement for the autoists—the State authorities are conducting a series of tests of the York county limestones and other rocks and it has been found that they are almost perfect for the construction of good roads.

As far as the investigations have extended, limestones, as a rule, are too soft, and most of the twenty-eight varieties have too small binding or cementing value to be used alone. The ad-

dition of harder stone in equal proportions to the limestone, some of this stone of local origin, has led to very gratifying results. A number of experiments are now under way to prevent any mud or dust on improved State roads, and several of the recently completed sections have been treated with surface applications and with marvelous success.

The Postdam sandstone of the ridge north of Hellam was found to have even less binding or cementing value, though two-thirds harder than material required for durable highways.

**National Character of the Chicago Show.** Ever since there have been two rival organizations in the field they have seen fit to bury their differences on at least one point, and that has been the matter of exhibiting under the same roof at Chicago, whence comes the claim of the latter city to house the only national show of the year held in this country. When first made three years ago this was looked upon merely as characteristic of the Windy City, and not as implying a great deal, but in the interim it has come to mean all that the word signifies, for in no other gathering of automobile and accessory makers of the year is there brought together such an imposing aggregation of manufacturers, nor one so truly representative of the American industry as a whole. The imported car was always a weakly exotic that found it hard to flourish so far from the Atlantic, and never cut much of a figure at the Chicago show; now it is practically a minus quantity, and in this respect Chicago's gathering has always had more of an American flavor than any of the Eastern functions.

In presenting the largest collection of automobiles and automobile accessories ever brought together at one time, to the public, Chicago does so imbued with that spirit of enthusiasm which is characteristic of the manner in which she undertakes anything, and which shows that a thousand miles, more or less, is almost sufficient to insulate her from the influence of Wall street. There is no cloud of depression overhanging the Coliseum and its numerous annexes such as cast a pall over the in-

itial Eastern event, and makers and dealers are arriving by the hundred, eager to do the business that they know awaits them, and confident that the outcome of next season will more than justify their plans. Chicago's show, as a whole, is the greatest achievement of the kind ever carried out in the shape of a purely industrial exhibition, and there is no doubt that the largest business ever done at an automobile show will be transacted during its week of strenuous activity.

Realizing that the two New York shows will be rolled into one at Chicago, many have waited for the Western exhibition rather than journey to the metropolis and spend double time. Here's to the hustling city on Michigan's shores!

**Improving the Automobile Just as a chain cannot be any stronger than its weakest link, so the strength and reliability in action of the highest development in automobile design and construction has, as a limiting factor, some one part of the car, the failure of which means disaster to its occupants. It is generally conceded that this part is the steering gear, and, judging from the overlong list of fatalities attributed to it, the type of construction favored by current practice would appear to be lamentably deficient in more than one respect. Doubtless the chief of these is the fact that the weight of the car is, perforce, borne on an accessory construction, so to speak, rather than directly on the axle, as has been the custom with horse-drawn vehicles from time immemorial. In other words, the inherent weakness of the present-day automobile steering gear would appear to be centered in the use of steering knuckles. Theoretically speaking, this may be true, and the fact that two inventors have evolved devices in which the load is borne directly by the axle, demonstrates the fact that the steering knuckle is not an unavoidable evil.**

However, the frequency with which other and equally essential parts of the steering gear are found to be at fault, while these reputedly weak members remain intact, amply indicates that improvement is not a matter of reforming practice in one respect alone. Starting at either end, whether at the steering knuckle or the steering mechanism itself, there appears to be no doubt that considerable refinement in detail must be brought about before the high speeds of which the automobile is capable can be characterized as safe. High speed in itself is naturally an element of danger, and many of the casualties hastily attributed to "a defective steering gear" have been due rather to the car's speed than to any failure of its parts. Nevertheless, that there is a great deal of room for improvement is strikingly illustrated by the many casualties in which the steering gear really proved to be at fault.

**The Need of a Strong National Organization.** If the automobilists of this country desire to bring about uniform laws governing the use of motor-driven vehicles and the building of good roads over which to drive them, they must realize the absolute need and great influence in these directions which can be secured through the strengthening of the American Automobile Association by the formation of clubs wherever possible and the addition of these clubs to the various State bodies, either formed or now in process of formation. The club wields a powerful local influence, the State association holds sway in State matters, and the national organization, while continuing the pioneer work of establishing new State bodies, finds time to assist, within its powers and scope, the State associations already at work. No administration of the A. A. A. ever deserved so well the support of automobilists generally, including the manufacturers, as the present continued régime headed by William H. Hotchkiss. Only by local, State and national organizations can things be accomplished, and this is exactly the plan of A. A. A. work, and its efficacy is plainly illustrated by an increase of over 11,000 in membership in less than a year.

**A. A. A. CHAIRMEN AND EXECUTIVE COMMITTEE.**

President William H. Hotchkiss of the American Automobile Association has announced the appointments of the chairmen of the following boards for the fiscal year beginning December 1, 1907:

Legislative Board—Charles Thaddeus Terry, New York.  
 Good Roads Board—Robert P. Hooper, Philadelphia.  
 Touring Board—Frank B. Hower, Buffalo.  
 Racing Board—Jefferson DeMont Thompson, New York.  
 Technical Board—N. H. Van Sicklen, Chicago.  
 Publications Board—A. G. Batchelder, New York.

The selection of chairmen for the Legislative, Good Roads, Touring, and Racing boards are reappointments, while the Technical and Publications boards are new, having only recently been authorized by the Board of Directors.

The Technical Board will conduct during the next year several contests of a technical nature, and as soon as organized will frame rules and plans accordingly.

The duties of the Publications Board will rest chiefly in the preparation of the A. A. A. Year Book for 1908.

The chairmen of the boards are now selecting the committee members to be nominated to the president for appointment and approval by the Board of Directors.

President Hotchkiss has also announced the new Executive Committee of the association, which will have charge of the association's affairs for the fiscal year beginning December 1, 1907, subject to approval at the regular quarterly meetings of the entire Board of Directors. This committee comprises seventeen members, or ten more in number than its predecessor, this increase having been authorized at the recent annual meeting. The membership now consists of four officers, six chairmen of boards, and seven directors at large, as follows:

William H. Hotchkiss, Buffalo; Lewis R. Speare, Boston; George E. Farrington, East Orange, N. J.; Charles T. Terry, New York; Asa Palne, Minneapolis, Minn.; N. H. Van Sicklen, Chicago; Jefferson DeMont Thompson, New York; Frank B. Hower, Buffalo; Robert P. Hooper, Philadelphia; A. G. Batchelder, New York; Stanford L. Haynes, Springfield, Mass.; F. T. Sholes, Cleveland; Paul C. Wolff, Pittsburgh; Harry M. Rubey, Macon, Mo.; L. E. Myers, Chicago; James T. Drought, Milwaukee, Wis.; Frederick H. Elliott, New York.

The geographical distribution of the committee covers ten States, of which there are six in the Middle West. The first meeting will be held in the First Regiment Armory, Chicago, Friday, December 6, at which time the policies of the association for the ensuing year will be discussed.

The plan of government of the American Automobile Association provides for the election by the local club of its directors in the State body, with the State boards of directors naming representatives on the national board. The clubs are supreme locally, looking after affairs in their respective territories, the State associations attending to State matters, with additional help supplied by the national board.

About four-fifths of the membership of the national board is nominated directly by the State bodies, the others representing unfederated clubs in States wherein organization is yet to be effected. The plan has proven its feasibility during the past year, the A. A. A. having more than doubled its membership, with the number of State bodies more than trebled.

**ENGLAND ABANDONS LIMITED FUEL RACES.**

LONDON, Nov. 19.—Announcement is made by the Royal Automobile Club that no further Tourist Trophy races will be held on the Isle of Man on a limited fuel basis. Next year an endeavor will be made to conduct a speed event of about 350 miles, providing the permission of the authorities of the island can be obtained. The race will be based on maximum bore and minimum weight, rating not to exceed 64, with the formula  $D2n$  ( $D$  the diameter of cylinder in inches and  $n$  the number). Minimum weight will be 1,800 pounds, exclusive of driver, spare parts and tools. The event has been dubbed the "four-inch race," for that will be the bore obtainable under the rules.

**SUDDEN DEATH OF GEORGE H. DAY.**

George H. Day, who had recently resumed his active connection with the automobile industry by again becoming a member of the executive committee of the Association of Licensed Automobile Manufacturers, died suddenly of heart disease at Daytona, Fla., on Thursday, November 21.

Mr. Day was a prominent figure in the American automobile industry from its inception, as it was he who brought the A. L. A. M. into being, and it was his executive ability, as manager of the association, that developed its possibilities and influence to the present state of efficiency. He served in this capacity up to the winter of 1906, when he retired on account of ill-health, going to Florida to recuperate, but at the request of a number of his confrères in the association again became a member of the executive committee last summer.

Mr. Day was born in Brooklyn in 1848 and was a graduate of Hobart College. He was appointed vice-president and general manager of the Pope Bicycle Company by Colonel Albert A. Pope when the latter acquired the old Weed Sewing Machine Company, and later became president of the Electric Vehicle Company, from which he resigned to guide the destinies of the licensed association. Mr. Day was a director of the *Ætna* Life and the *Phoenix* Mutual Life Insurance companies, the American National Bank, the Fidelity Trust Company, and the Society for Savings. He was a trustee under the will of Mrs. Elizabeth Colt, and secretary and treasurer of the Colt Bequests Board of Trustees.

GEORGE H. DAY.  
 Photo taken at Daytona,  
 Fla., January, 1907.

He was a member of the *Aldine*, the *Engineers'*, the *Lawyers'*, the *Alpha Delti Phi*, and the *New York Athletic* clubs, and the *Automobile Club of America*. His wife, who was Miss Katherine Beach, daughter of J. Watson Beach, and four children survive him. The funeral services were held at his late home in Hartford.

**EVENTS DURING THE CHICAGO SHOW.**

Wednesday, December 4, 10 A.M., Meeting Executive Committee of N. A. A. M., First Regiment Armory.  
 Wednesday, December 4, 11 A.M., Meeting Committee of Management American Motor Car Manufacturers' Association, New Southern Hotel.  
 Thursday, December 5, 10:30 A.M., Meeting Mechanical Branch A. L. A. M., Chicago Athletic Club.  
 Thursday, December 5, 11 A.M., Meeting of Executive Committee American Automobile Association, First Regiment Armory.  
 Thursday, December 5, 2:30 P.M., Meeting Illinois State Automobile Association of A. A. A., Chicago Automobile Club.  
 Thursday, December 5, 8 P.M., Meeting Chauffeurs' International League of America, Auditorium Annex.

The Paris Prefecture of Police has recently enforced the law against smoking exhausts on automobiles with severity. Several drivers have been fined heavily and have in one or two instances been sentenced to prison for short terms. To use search lights within the city limits or to operate a siren, except in the open country, are two other offenses never overlooked by the bicycle "cops." This has, however, so long been recognized that only foreign visitors are now caught.

## A NEW VOCABULARY FOR A NEW INDUSTRY

"BY what authority came the word chauffeur to be foisted on an English-speaking public?" The question is often asked privately and from time to time some indignant pure-speech-loving enthusiast echoes the same query through the columns of the daily press, with an appeal to the potentate of the blue pencil to use all his power and influence to exterminate the foreign intruder.

There are about a dozen other words, as foreign to the average man ten years ago as ancient Greek, which have gradually slipped into everyday use until to-day they pass unquestioned, and have, by their mere persistence, earned a place for themselves in the latest editions of national dictionaries.

It is one of the rules of life that a nation which has the honor of introducing anything new in any department of activity should impose its own nomenclature. There are sufficient examples in our own products adopted by speakers of other tongues and allowed to retain their native names to warrant accepting a few from outside. Because France got a few years' advance on the world in the introduction of the automobile she had to supply a new set of terms to cover the nakedness of her new creation. "Automobile" suggested itself, nothing being simpler than the combination of *auto*—self and *mobile*—moving. But before automobile was allowed to pass as a substantive it was used in connection with carriage, the new vehicle being a *voiture automobile*, or automobile carriage. As every noun in French must be of either masculine or feminine gender it had to be decided which class automobile should go into. As *voiture* is feminine some declared that automobile should be of the gentle sex, too; others took up the opposite side, and an academic division was produced. Even now it is not certain in the land of its creation, whether an automobile is a "she" or a "he."

"Chauffeur" is an interloper—an interloper who cannot give one solid reason why he should have been allowed to creep into the automobile language. Before self-moving road vehicles came into being chauffeurs were found only on railroad engines, steamships and stationary steam engines, their duties being to feed their charges with coal. Why the driver of an automobile should have been called a chauffeur it is difficult to understand, for his prototype on steam engines had nothing whatever to do with driving, that task being left to the *mécanicien*, and even the first automobiles, crude as they were, had little in common with a stokehole.

The further one goes back the less glorious is the ancestry of the chauffeur. In the dark days of the French revolution armed bands took advantage of the weakened executive power to roam through the land and rob all and sundry. A favorite method of persuasion when the terrified natives refused to reveal the spot in which their treasure was hidden, was to *chauffe* or burn the feet of the unfortunates. Frequently, in those cold winter nights the *chaufferette* or bed warmer, was seized upon as the convenient instrument of torture. So extensive were the depredations of these bands that for a time chauffeur and brigand were synonymous terms.

A garage is merely a shelter, with nothing in its make-up to indicate that it has any connection with automobiles. The connection is easy to see between *garage* and *gare*, a railroad station. A garage line on the railroad is merely a siding; when it was necessary to christen the home of the automobile, it was more natural that the locomotive should be godfather and not the horse stable.

As at present applied, chassis is just a little younger than the automobile industry. In earlier days it designated any kind of wood or metal frame, from a wooden cucumber frame to the metal framework of a railroad coach. It is only by common consent that chassis has obtained its present-day significance; originally it meant the side members and cross sections, nothing more in fact than the framework on which the mechanical organs

are attached. Little by little its field of influence was enlarged, until now it is generally understood to mean the entire mechanical part of the automobile. Whether used in the singular or the plural, its termination is the same, *chasses*, which occasionally finds its way into print, being altogether incorrect.

Georges Huillier, one of the directors of the Mors factory in Paris, is responsible for elevating the tonneau from a humble field of usefulness as a wooden cylindrical chamber for containing wine or beer, into a dignified position as part of the automobile. At a time when automobile carriage work was without form and void, Huillier produced a new design of body with rear entrance and rounded ends, to be fitted on the chassis in the rear of the driver's seat. Roughly it resembled a barrel cut across the middle; as no more suitable term could be discovered, it was called a barrel—for tonneau is merely the French for barrel—and has remained a tonneau, in the English language, despite radical changes in its design. In French modern side entrance touring cars have ceased to be known as tonneaux, the type developed from the rear-entrance barrel-shaped body being a double phaeton.

Down in the old-world Department of Correze, in France, known under the old régime as Bas-Limousin, the peasants wear a heavy full footed wooden sabot, known locally as a limousine. The district has also a particular type of closed carriage a sort of small stage coach, the design of which, in this unchanging country, has probably not been modified in ages. A coachbuilder from Limoges established himself in Paris, produced a new type of open vehicle and named it limousine in honor of his homeland. From an open vehicle the name began to mean a completely closed carriage and with the automobile its importance has grown until now it designates the most luxurious type of touring body; the peasant's wooden shoe, however, has not renounced its right to the title.

Bavaria appears to have given birth to the landaulet, with a type of vehicle fitted with a folding top, and known as a Landau, after the town of Landau, in which it originated. It was modified, slightly reduced in size, and a few more letters added to its title. Taximeter had to be created to meet a modern need for a handy term to designate a vehicle that will doubtless play an important part in every-day life. Some advertising agents appear to have assumed that a taximeter is a special type of automobile, forgetting that the box of clockwork in itself no more modifies the vehicle on which it is placed than the gas meter changes the nature of the gas. It is merely a combination of *taxi*, a tax and *metre*, a measure of distance, designating the instrument which taxes according to distance. On its introduction it occasioned a little trouble, some users being in favor of *taxametre* and others claiming *taximetre*; after some discussion etymologists declared the latter form the only correct one, and it has remained.

Jerome Cardan has long laid in his unknown resting place, and his mathematical researches have so passed into the sea of knowledge as to be almost forgotten as individual efforts. The universal joint which his fertile brain created, and which was first known as Cardan's joint or joint à la Cardan, was never in danger of dying out, but its application was somewhat limited and its admirers were few until the automobile came along and brought it into public favor, four centuries after the death of its inventor.

### ARRANGEMENTS FOR THE CLEVELAND SHOW.

CLEVELAND, Nov. 25.—Although the date of the Cleveland show has been definitely set for the week of February 17, the Cleveland Automobile Dealers' Association held a meeting recently in order to decide upon some of the preliminary arrangements. George Collister, who has had charge of most of the Cleveland shows held in the past, will also have the management.

## INCREASED ACTIVITIES OF LEADING A. A. A. CLUBS

### PHILADELPHIA'S FORCEFUL A. A. A. CLUB.

PHILADELPHIA, Nov. 25.—Having just reached the goal set less than a year ago—the 500 membership mark—the Automobile Club of Philadelphia has decided to go ahead and endeavor to double this figure. Conservative to a degree, the Automobile Club of Philadelphia officials, while little heard of in the promotion of track and road events, is yet a powerful factor in the defense of autoists' road rights hereabouts and in the State at large, in route-making and the other details which add to the comfort of the tourist.

In this latter respect the club has done a grand work. Quietly and without the "press work" which has been such a marked help to the lesser local clubs, the Automobile Club of Philadelphia has gone quietly about its work of sign-boarding the main routes leading from Philadelphia to the neighboring large cities and resorts. At its own expense the Philadelphia-Trenton and Philadelphia-Reading routes have been thus marked, every point where a possibility of the tourist taking a wrong road exists having been decorated with a large signboard setting forth the distances to the nearest large towns and the directions. The roads to Gettysburg and Harrisburg, to the Delaware Water Gap, and to Baltimore are being carefully gone over by the club's agents, with a view of not only discovering the best and most direct routes, but of avoiding as far as possible the ubiquitous toll-gate, which makes touring to and from the Quaker City one continuous process of "digging down into one's jeans." As a result the club's committee having charge of this work has definitely abandoned the much-traveled route to the north via Easton and decided on that via Bethlehem as not only shorter but equally good and much less expensive. On this route, therefore, the club will set its markers.

The direct route to Baltimore via Wilmington being at present almost impracticable for comfortable touring, and that via Hanover and York much too long, the club's agents are at work on a compromise route which will be announced, when a short connecting link, now in poor condition, is put in proper shape.

The club's law committee, under the chairmanship of S. Boyer Davis, is also doing excellent work, having just issued a compact digest of the automobile laws of Pennsylvania and all adjacent States for the benefit of tourists. Besides this, the committee has done effective work in protecting the interests of those of its members whose rights have been endangered through the overzealousness of borough, township and county officials.

It is along these lines that the club's officers believe that the club's energies may be most effectively directed, and the result in the increase of membership gives evidence of the wisdom of their course. Without endeavoring to detract in any manner from the policies of other local automobile organizations, it cannot be denied that in the long run the benefits to automobilists generally—not excluding the trade—resulting from the efforts of the Quaker City's oldest automobile club, are becoming more and more apparent to the great army of "unattached" automobilists hereabouts. Therefore it can hardly be said that the 1,000 membership mark which the Automobile Club of Philadelphia officials have set as a goal, and which they expect to reach by the close of the year 1909, is not too ambitious.

Long before that time, in all likelihood, the club will have built its own home. Indeed, the demand for a central headquarters such as the big New York organization now boasts is becoming insistent and the first steps toward that much-to-be-desired consummation have already been taken. Several of the club's more prominent members have for the past year been quietly looking over the ground, and it is quite possible that an official announcement along these lines will be made public early in the coming year.

### COMPEL TOWNS TO PROVIDE SIGNBOARDS.

ALBANY, N. Y., Nov. 25.—President Oliver A. Quayle, of the New York State Automobile Association, has been on a legal hunt in the archives of New York's forgotten legislation, and as a result of the successful outcome of his quiet investigation he is now sending out notices to New York State clubs which will come as considerable of a surprise to the majority of their members—even those who follow the law. The act he ferreted out was evidently passed at the instance of cycling interests, and constitutes Chapter 330 of the Laws of 1895, being an amendment to the highway law relating to the erection of guide boards and posts upon highway intersections. It makes the erection of such signs a part of the duty of highway commissioners generally, and, what is far more important, provides that, upon the written application of any five resident taxpayers of any town, or twenty resident taxpayers of any county, the highway commissioners shall have such signs erected as are requested in the petition, their further cost and maintenance being a town charge. Neglect or refusal to comply with such requests is punishable by a fine of \$25. That probably not one person in a thousand was aware of the existence of such a law is evident from the fact that so many clubs have been doing this work at their own expense. The law is as follows:

AN ACT to amend the highway law relating to the erection of guideboards and posts upon highway intersections.

The People of the State of New York, represented in Senate and Assembly, do enact as follows:

Sec. 1. Section five of the highway law is hereby amended to read as follows:

Sec. 5. Milestones and guideboards. Commissioners of highways may cause mileboards or stones to be erected upon the highways in their town as they think proper; they shall also cause guideposts, with proper inscriptions and devices, to be erected at the intersections of such highways therein, as they may deem necessary, which shall be kept in repair at the expense of the town, by the overseers of the highways of the districts in which they are respectively located. Upon the written application of five resident taxpayers of any town, or twenty resident taxpayers of any county in which the town is located, to the commissioner of highways, requesting the erection of one or more guideboards at the intersection of highways in such town, the commissioner of highways shall cause to be erected at the intersections mentioned in such application, such guideboards, indicating the direction, distances and names of towns, villages or cities to or through which such intersecting highways run. Such application shall designate the highway intersections at which such guideboards are requested to be erected and may contain suggestions as to the inscriptions and devices to be placed upon such boards. The cost of the erection and maintenance of such boards shall be a town charge. If the commissioner of highways refuses or neglects, for a period of sixty days after receiving written application, to comply with the request contained in such application, he shall for such neglect or refusal forfeit to the town the sum of twenty-five dollars, to be received by the supervisor in the name of the town, and the amount so recovered shall be set apart for the erection of such guideboards.

### WORCESTER CLUB'S ANNUAL BANQUET.

WORCESTER, MASS., Nov. 25.—The Worcester Automobile Club had its fifth annual banquet last Thursday night, and the members who have been at most of the annual affairs of the club say it was the best in the history of the club.

"Modes of Travel and Transportation" was the theme on which the after-dinner speaking was based. Frank Roe Batchelder was toastmaster. No speaker was obtained for the aerial topic, but a letter from Dr. Julian P. Thomas of the Aero Club of America was read, and this was a good substitute for an address. Secretary Frederick H. Elliott of the American Automobile Association spoke for the autoists. He devoted his address to the A. A. A., what it has been doing and what it intends to do in the future. He gave the members of the club and their

friends the clearest idea of the work of the A. A. A. they have received in a long time.

Speakers on other lines were: Steam railroads, Charles A. Waite, general agent for the Boston & Maine Railroad; electric railways, Edward G. Connette, general manager of the Worcester Consolidated Street Railway Company and of the New Haven trolleys in this section of the country; John F. Kyes spoke for the bicycle and told stories of the precursor of the automobile; Attorney Webster Thayer spoke for the horse and his drivers; and Representative Robert M. Washburn spoke for the people who walk.

A feature of the banquet was a string of parodies on popular songs, with grinds on the officers and members of the club. Dr. A. J. Harpin led in the singing and the company was strong on the chorus of each.

President W. H. Chase of the Wachusett Automobile Club of Leominster, Attorney Francis Hurtubis, Jr., of Boston, counsel for the Massachusetts State Automobile Association; Mayor John T. Duggan, who responded for the city of Worcester, and Chief David A. Matthews of the Worcester Police Department were guests of honor at the banquet.

#### BAY STATERS TO DISCUSS PERTINENT SUBJECT.

BOSTON, Nov. 25.—The Bay State Automobile Association will open its winter social season next Saturday evening with the first of a series of smoke-talks, open to members and their friends. As there is no apartment in the clubhouse on Dartmouth street capable of holding a large assemblage, the meeting will be held in the Hotel Oxford nearby. The subject selected for discussion at the opening gathering is "The Co-operation of automobile clubs in the enforcement of the automobile law." This is a subject of great interest to all automobilists, and the association has secured as leaders in the discussion Chairman W. E. McClintock of the Massachusetts Highway Commission, which administers the automobile law in this State; Lewis R. Speare, vice-president of the American Automobile Association and chairman of the legislative committee of the Massachusetts State A. A., and Mr. Crowley, a young Boston attorney who has made a special study of the automobile law.

The association is also making preparations for its annual banquet, which will be held on the evening of December 10 at the Hotel Somerset. The committee in charge of the arrangements is assured of a good attendance and is planning to invite some prominent men in the automobile world to make the after-dinner speeches.

#### MASSACHUSETTS BODY CHANGES FISCAL YEAR.

BOSTON, Nov. 23.—At a meeting of the board of directors of the Massachusetts State Automobile Association, held in this city last Thursday, it was decided to change the date of the annual meeting from April to October, thus giving new officers all winter to prepare for their duties, instead of entering upon them at the beginning of the outdoor season. The directors also voted to adopt a new set of by-laws for the association. A general meeting of representatives of the various clubs which are members of the State association will be held next month, for the purpose of discussing the attitude which the association shall take in the subject of legislative matters at the next session of the General Court. Several important laws affecting automobilists will be proposed, and the association is thus early getting ready to look out for the rights of its members and all other automobilists.

#### ANNUAL DINNER OF LONG ISLANDERS, DEC. 6.

BROOKLYN, N. Y., Nov. 25.—The annual meeting of the Long Island Automobile Club will be held Wednesday, December 4, at 8:30 P.M., at which time annual reports will be read and officers elected for the ensuing year. The seventh annual banquet will be held Friday evening, December 6.

The Runs and Tours Committee announce that the touring season will close November 30. Odometers which were registered at the clubhouse at the beginning of the touring season, in connection with the mileage trophy, must be registered with the club's manager, Mr. Creighton, on or before that date. The committee suggests that members who have good mileage scores shall not overlook this requisite. The mileage trophy, offered by James Edward Bristol, will be presented at the annual dinner to the member whose odometer shows the highest registration. The touring trophy, offered by Willard P. Reid, will be presented on the same occasion to the member who has toured in the greatest number of States and provinces during this season.

#### SECRETARY BONNELL OUT OF DANGER.

NEWARK, N. J., Nov. 25.—H. A. Bonnell, the hard-working secretary of the New Jersey Automobile and Motor Club, who was recently operated upon at St. Luke's Hospital for appendicitis, is out of danger, and it is expected that he will be able to go to his home in East Orange in another week. It will be remembered that Mr. Bonnell was taken ill during the recent 24-hour endurance run of his club, but he insisted upon remaining on duty until the completion of the event.

The club committee this week will decide on a design for the silver cups which will go to the eight winners, the Oldsmobile entered by R. A. Greene having been added to the list of clean-score cars. It was found that the observer noted the slipping of a clutch and charged the driver with the time he spent in putting chalk on the clutch to avert a repetition of the slipping. The motor of the car was not stopped.

#### A. C. OF BUFFALO ANNUAL MEETING.

BUFFALO, N. Y., Nov. 25.—The board of directors of the Automobile Club of Buffalo has amended the by-laws so that hereafter the board will consist of five members, instead of three members, and the officers, as has been the custom ever since the organization of the club. This action was deemed advisable on account of the big increase in the membership during the last two years. The annual meeting of the club will be held in the clubrooms the evening of December 16. Nominations will be announced December 1. The second entertainment to be given this winter will take place on the night of election.

#### FIRST TO NAVIGATE NEW HARTFORD BRIDGE.

HARTFORD, CONN., Nov. 25.—With Ralph Barkman, city sales manager of the Pope Motor Car Company, at the wheel, a new 1908 Model M Pope-Hartford car earned the distinction of being the first to essay crossing the new but yet incomplete bridge across the Connecticut river to East Hartford to-day, the photo showing the car and its occupants on the trip.

POPE-HARTFORD CROSSING NEW BRIDGE AT HARTFORD.

VICE-PRESIDENT FAIRBANKS, GOVERNOR GILLETT, AND SENATOR FLINT OF CALIFORNIA, AT STANFORD UNIVERSITY, PALO ALTO, CAL.

**THE CHAUFFEUR'S MORAL CODE.**

Realizing the fact that dissatisfaction over the service rendered by a commercial vehicle is due far more often to the driver than to any other cause, the Firestone Tire and Rubber Company, Akron, O., have prepared a code for the conscientious driver to follow. It is made in the shape of a large and very ornate certificate embellished with the usual seal and ribbon and is intended to be hung on the wall. Its preamble is as follows:

This certifies, that the Commercial Motor Vehicle Chauffeur possessing this document, has the interests of his vehicle at heart, and, unmindful of the yearnings of the Repairman and Junk Dealer, hereby adopts the following:

(1) I will not overload or overspeed my vehicle because this will be harmful to the mechanism and tires. I realize that a good rubber tire has a certain amount of "life," and if persistently over-worked it cannot recover.

(2) I will always keep the brakes working evenly and the axles and wheels "trued up." I can thereby save rack and wear on my vehicle and prevent unnecessary strain on any one of its tires.

(3) I will not allow oil or grease to accumulate on my rubber tires, as this will eventually cause decay.

(4) I will never expose my tires to burning heat, as the wear-resisting properties of the rubber would thus be destroyed.

(5) I will always remember to start my vehicle in a straight line before turning the steering wheel; because by turning front wheels when vehicle is standing still a heavy and unnecessary strain would be placed upon the tires.

(6) I will start and stop my vehicle gradually and avoid jerky motions under all circumstances.

(7) I will not persist in running my vehicle along street car rails, as that would grind down the edges of the tires.

(8) I will always, when possible, choose a smooth pathway, avoiding obstacles and road irregularities; and will cross car tracks preferably at an angle.

(9) As merely resetting or repairing a tire will, in many cases, double its life, I will have my tires attended to promptly when damaged, in order to secure the greatest amount of service from them.

(10) And above all things, I will use my influence to have my vehicle equipped with the best tires that are made—Firestone Side-Wire motor tires.

**THE GERMAN EMPEROR'S NEW CARS.**

Three new Mercedes cars have been recently supplied to the German Emperor, two for his own personal use and one for the Empress. Her Majesty's car is a 45-horsepower landaulet, while the Emperor has kept pace with the times by purchasing a very handsome six-cylinder of 75-horsepower, a huge touring car, able to fulfill his love for speed. The other vehicle is a 60-horsepower four-cylinder phaeton. The garage staff consists of three head drivers, seven ordinary chauffeurs, and ten servants, who accompany the drivers. All of these wear buff uniforms and the chief chauffeurs carry an armshield. The whole is under the management of Lieutenant Zeys, with Baron von Reischach, chief of the Imperial stables, at its head and Werner as chief chauffeur.

**DENVER FRANKLINITES MADE MERRY.**

DENVER, Nov. 25.—"Bilz" is not simplified spelling for those unwelcome visitors that Uncle Sam delivers around the first of the month—it's part of the cognomen of Charles Bilz, who is the Denver distributor of the Franklin cars, and whose garage is at 1432-38 Court place. A few nights ago he entertained Denver Franklin owners—gave them a right royal time, and he paid the Bilz. This took the form of a dinner and vaudeville show at the Albany and proved a most enjoyable affair. The menu card was novel and characteristic, the fun fast and furious, and according to all present everything was "all right." Denver owners are certain that Bilz is as good as the car he handles.

**HOW IS THIS FOR FAST TRAVELING?**

Autoist to Saint Peter: One and two-tenths seconds from the earth! Isn't that a record.—*Blätter für Sport-Humor.*

### AN IMPROVED FORM OF STEERING GEAR.

Quite a radical departure from current practice in steering-gear construction is represented by the Murray steering mechanism, here illustrated, and in which the load is designed to be borne entirely by the wheel and axle, so that shocks are not transmitted to the steering-gear. The wheel is pivoted on a trunnion placed in the hub and the axle terminates exactly in the plane of the spokes, the steering connections being made in the usual manner. The axle itself may be of any type, provided with a forked end to carry the trunnions. The latter are fixed to a journal with two bearing surfaces, a large one in the plane of the spokes and a smaller one, outside this plane. A spindle revolves axially inside this journal and is fixed in the hub of the wheel by a bolt.

FIG. 1.—Illustrating the steering connections.

The wheel proper is made with a large recess to admit the larger diameter of the journal with its roller bearings, and a second recess for the other set of bearings. Forming part of the journal bearing is an arm engaging the reach rod of the steering system, by means of which the wheels are moved. Most of the weight of the car thus falls on the larger bearings, and these are reinforced by a second set in another plane.

FIG. 2.—Details of wheel and axle assembly.

The axle is rigid to the end and the latter point is brought within the plane of the wheel, carrying the load as if it formed a direct bearing for the hub, from which it will be apparent that it has been the aim of the designer to evolve a steering mechanism which shall combine all the manifest advantages of a simple wheel and axle, at the same time producing a method of steering that shall be more positive as well as more reliable than present practice permits. James E. Murray of McKeesport, Pa., is the inventor, and patents have been granted in the United States, as well as several foreign countries.

FIG. 3.—Method of mounting the wheel on the axle.

### CHANGE-SPEED GEAR ON NOVEL PRINCIPLE.

The use of a cone has long been common in connection with belt-driven machinery for speed-changing, but the "R-W Speed Variator," which is illustrated by the accompanying photograph, is a novel departure from previous practice in this respect, in that it combines the principle of both the cone and gearing, thus insuring a positive drive. The method of effecting the speed changes is of considerable interest, having been very ingeniously worked out. The "gear-cone" is provided with a number of circumferential rows of "gear pits," while parallel with the slant of the cone is a shaft on which is feathered a spur pinion having pin teeth of a general conoidal form. This gear is movable longitudinally on its shaft, so as to bring it into mesh with any desired row of pits on the cone, thus causing the driven element, which may be either the gear or the cone, to rotate at a corresponding speed. The circular rows of pits are so arranged that one of each row is exactly in line with the correspondingly located pits in all the other rows. This straight or longitudinal series of pits is formed on a sliding bar capable of movement in either direction, a distance equal to the space between successive circular rows of pits. Consequently, if at the moment in the

NOVEL MECHANISM OF THE R-W SPEED VARIATOR

cone's rotation when the slide is parallel with the gear shaft the slide be shifted, it will carry the gear to the next row of pits. At the base of the cone are two grooves, which the slide crosses, while projecting from the slide into the grooves are two studs, the arrangement being such that when the slide is in its normal position these studs are spaced slightly from the rib between the grooves. Adjacent to the grooves are two oppositely inclined cams, each equal in width to the distance the slide must move to transfer the gear from one row of pits to the next, so that the cams engaging the stud on the slide will shift the slide the proper distance. These cams are mounted on the upper ends of two arms pivoted at their lower ends, the arms being connected by links to a controlling lever on opposite sides of the pivot of the latter, this method of connection making it impossible to throw both cams into the operative position, and to produce the necessary rotation the moment the operator releases the controller a spring-controlled plunger is provided. This has a flat face bearing against the controller on both sides of the pivot, so that oscillating the controller in either direction compresses the spring, and this, upon releasing the lever, immediately throws the lever to the inoperative position with both cams retracted. To restore the slide to the normal position after each actuation, an inclined member is provided at each side of the flanges at the base of the cone, against one or the other of which one of the side lugs strikes after passing the gear. As long as one of the cams is held in its groove each revolution of the cam will produce a movement of the slide and a corresponding shifting of the gear, so that the latter moves, step by step, up or down the cone, according to which cam is in operation. To prevent damage from failure to retract the cam when the last step is reached, this is withdrawn automatically by mechanism placed in the cone itself.

### DEMONSTRATING A 14-H. P. WALTHAM.

Few better illustrations of what the modern light commercial vehicle of the gasoline-driven type can accomplish in the way of economy and reliability have ever been afforded prospective purchasers of such cars than the recent round trip of the 14-horsepower, water-cooled Waltham "Parcel Car," from the home factory to New York and return. On the run to the metropolis, the distance of 244 miles was made in 12 hours and 40 minutes on a fuel consumption of 15 gallons and one gallon of lubricating oil. Three passengers and a load aggregating 875 pounds were carried, in spite of which it was only necessary to drop to a lower speed on but four occasions throughout the trip, in order to mount particularly bad grades or overcome poor going.

The car was run to New York just prior to the opening of the Garden show and was run around the city throughout the week of the latter for demonstrating purposes. The car is friction-driven, and one of the favorite tests for showing its ability was to bring it to a standstill on the steepest part of the Fourth avenue hill, starting again on the high gear without first speeding the motor. Following the show, the car was taken to Newark, N. J., for the purpose of making demonstrations for the Newark agents, the H. J. Koehler Sporting Goods Company, one of its feats consisting of taking a hill that is said to be the favorite stamping ground of demonstrators in showing high-powered pleasure cars. The car was stopped and started again on the worst part of the hill.

On the return trip demonstrations were made at New Rochelle, N. Y., Waterbury and Hartford, Conn. On arriving at the factory the car was weighed and found to tip the scales at 1,600 pounds, and, with the load it had carried, 2,475 pounds. The car was dismantled and all its working parts examined. It was found that the 900-mile trip had not been sufficient to cause the slightest amount of wear on any of the parts, the high-speed bevel friction surfaces in particular not showing any perceptible evidences of the hard service. The car was immediately reassembled and a much more ambitious trip undertaken, as it was started on its way to Chicago, the plan being to use it for demonstration purposes during the show week there, November 30-December 7. Although the roads between New York and Chicago are in a most unfavorable condition at this time no doubt is felt as to the ability of the Waltham to accomplish the journey.

### RECENT INCORPORATIONS IN NEW YORK.

Incorporation has recently been effected at Albany of the Recometer Company of America, with a capital of \$300,000, for the production and marketing of speed indicating devices. Directors are Frank W. Waggoner and Frank E. Carstarphen, 253 Broadway, New York; Daniel M. Miers, Hasbrouck Heights, N. J. The Fleur de Lys Automobile Company of New York has been incorporated with a capital of \$25,000, directors being F. Knowlton, 638 East 139th street; E. A. Monfort, 1350 St. Nicholas avenue, New York; E. D. Cronin, 277 Vanderbilt avenue, Brooklyn.

E. R. THOMAS ARRIVING AT HIS BUFFALO FACTORY IN A THOMAS TOWN-CAR.

### THOMAS TO BUILD A THOUSAND TAXICABS.

BUFFALO, N. Y., Nov. 25.—Announcement is made that the E. R. Thomas Motor Company has an order to build 1,000 taxicabs. It is reported here that two of the largest New York hotels will replace their hansoms with these cabs. Much new machinery is to be installed by the Thomas company in order to meet the sudden demand for this class of conveyance.

The Thomas Motor Cab Company has been incorporated to operate taxicabs. The certificate was filed in the County Clerk's office last week. It is capitalized at \$50,000. Directors are E. R. Thomas, E. L. Thomas, and Arthur Z. Mitchell, all of Buffalo.

### E. R. THOMAS DETROIT CO. IN NEW PLANT.

DETROIT, MICH., Nov. 25.—The E. R. Thomas Detroit company is now operating in its new reinforced concrete factory out Jefferson avenue. The machinery has been turning for three weeks past and every department is now in full operation. Notwithstanding the delay incidental to moving from the old factory, production of the 1908 cars was carried on continuously, and deliveries have been going out to the agents ever since the first of October.

The rapidity of construction of this large plant is astonishing, as the contract was let May 15 and the plant was opened the latter part of September, fully equipped.

NEW REINFORCED CONCRETE FIREPROOF FACTORY OF THE E. R. THOMAS DETROIT COMPANY, ON JEFFERSON AVE., DETROIT.

## BRIEF ITEMS OF NEWS AND TRADE MISCELLANY

The Algonquin Motor Car Company, of Boston, succeeds the Henshaw Motor Car Company and will retain the same salesroom at 97 Massachusetts avenue, representing the Oldsmobile and Columbus Electric in New England.

One of Philadelphia's latest industries is that of tire-making, the product of the firm of Jas. L. Gibney & Brother attracting considerable attention at the recent show in the Quaker City. They are turning out side-wire types in singles and "twins" as well as the internally wired type in all sizes.

The Longacre Motor Company has succeeded the Manufacturers' Motor Car Company, at 54 West Forty-third street, New York City. H. Homey Hill is president of the new company, which has taken a lease of the adjoining buildings, at 44-52 Forty-third street, and will move as soon as alterations are completed.

The co-partnership heretofore existing between Harry M. Eastman and Ernest F. McCarthy, doing business under the firm name of H. M. Eastman & Company, Melrose, Mass., has been dissolved. Mr. Eastman will continue in the business, maintaining a garage and selling Cadillacs and Buicks.

The Northern Motor Car Company is also getting its selling force out on the road early, the following representatives already reporting a good business with excellent prospects. The territory is divided as follows: John W. Swan, Pacific Coast; L. E. Wood, Middle West; James H. Foster, Ohio and Indiana; A. G. Williams, East, including New England; J. L. Sternberg, West.

The progressiveness of the Continental Caoutchouc Company's manager, Joseph N. Gilbert, was in evidence at the recent Yale-Princeton football game, in the shape of a special Continental tire depot, temporarily established in Reichert's Palace garage, New Haven. Few events of any kind bring forth so many automobiles as came to the college city on that day, so that the foresightedness of the Continental manager in providing a stock of all sizes ready at hand to meet the emergency was apparent.

In chronicling the incorporation of the Regal Motor Car Company, Detroit, Mich., in THE AUTOMOBILE, November 14, the name was inadvertently put as "Royal" instead of "Regal," and while there is considerable similarity in the significance of the two words, the incorporators would naturally prefer to see the proper adjective employed. The company has been organized by Paul Arthur, trustee, and Robert Webster, with \$100,000 capital, \$51,000 of which has been paid in. Runabouts, touring cars, light delivery cars and town cars will be built.

The value of the automobile as a means of doing business is best realized by those connected with the industry, and while the ordinary salesman makes his rural rounds in an antiquated buggy with a "hay motor," or depends upon trolleys and accommodation trains, the up-to-date salesman gets over three times the territory in his car. This is the way in which E. M. McGookin, sales manager for the Stewart & Clark Manufacturing Company, gets over his territory in his Marion roadster, on which he has mounted an attractive polished metal sign bearing the words "Stewart Speedometer," so that all who run may read.

It sounds a bit paradoxical to say that insufficient inflation is sometimes the cause of tires "blowing out," but this comes from such an excellent authority as E. H. Broadwell, of the Fisk Rubber Company, who explains it this way: "When a tire is not pumped up sufficiently, the pressure of the ground on the under side has a tendency to loosen the several plies of fabric in the envelope of the tire, so that they rub together, or shuffle, as tire makers say. In this fabric, or friction cloth, is where quality and good work count tremendously for tire economy, and this is the reason Fisk tires are more expensively made and have one more ply of friction fabric than others of the same diameter. The rubbing together, or shuffling, of two plies causes the threads to break and so weakens the casing that the inner tube, with its high pressure, bursts through, or blows out. Old tires, therefore, more than new ones, should be properly inflated; not too hard, nor yet slack."

Figures recently compiled from the State automobile registration lists in Illinois and Wisconsin, show that the Rambler, made by Thomas B. Jeffery & Company, Kenosha, Wis., leads all other makes in numbers in those commonwealths. There are perhaps 13,000 cars registered in Illinois, but available lists show only 9,799, and of this number 738 are Ramblers. In Wisconsin the full registration, not including transfers, was, on August 1 of this year, 3,852. The Rambler leads in that State with 477. In Illinois complete figures have been difficult to get. Yet the total given covers the registration on practically all cars now in service. Next after the Rambler in Illinois in point of numbers comes the Cadillac with 658, while the Ford is third with 599. Illinois has 115 foreign cars and 369 electrics. Just 223 different makes are registered. Wisconsin official lists give the Rambler supremacy over all with a registration of 477. The others rank below the Rambler, as follows: Cadillac, 454; Oldsmobile, 232; Buick, 222; Ford, 221.

### NEW AGENCIES ESTABLISHED.

The Commercial Auto Company, of Milwaukee, and of which O. A. Eskuche and Mitchell Mackie are the principals, has taken on the line of the Logan Construction Company, Chillicothe, O., for the State of Wisconsin for the season of 1908. The concern has secured temporary quarters at 1103 Grand avenue and already have a full line of the Logan cars on the road demonstrating.

That agencies for the "Silent Northern" are rapidly being closed up for the coming season is evident from the appended list of those who signed within the last week or two: Copeland & Taylor, Pontiac, Ill.; C. W. Evans, Dixon, Ill.; Noah Keeler, Wallace, N. Y.; A. H. Ritter, Iola, Kan.; Enid Automobile Company, Enid, Okla.; Wilson Automobile Co., Wichita, Kan.; Huron Automobile & Electric Company, Port Huron, Mich.

### PERSONAL TRADE MENTION.

James R. Gilbert, formerly of the B. F. Goodrich Company, has entered the service of the Michelin Tire Company as assistant to C. C. Harbridge, manager of the Chicago branch.

Albert C. Galbraith has just entered the service of the Fisk Rubber Company and will travel from the latter concern's Philadelphia branch house, his territory consisting of Eastern Pennsylvania and Virginia.

Percy Owen, president of the New York Automobile Trade Association, has appointed Sidney B. Bowman a member of the committee on storage rates, the other members of this committee being W. H. Haradon, of the Victor Auto Storage Company, chairman, and G. A. Knowles, of the Locomobile Company.

J. Elmer Pratt has severed his connection with the sales department of the Cadillac Motor Car Company, where he has been for a long period as the general assistant of W. E. Metzger. Mr. Pratt, who has been a conscientious and hard worker, now intends to indulge himself in an innings of the open-air living, after which he will again get into harness.

T. F. Byrne, formerly manager of the Franklin Automobile Company, Chicago, has severed his connection with that concern to assume the management of the Eastern Automobile Company, Montreal. The latter company represent the Packard, Maxwell, Clément-Bayard and Napier cars and are also distributors of Diamond tires in that part of the Dominion.

### PRES. OF THOMAS DETROIT CO.

Hugh Chalmers, formerly vice-president and general manager of the National Cash Register Company, is one of the most notable newcomers to the ranks of the automobile industry. He has acquired a heavy interest in the E. R. Thomas Detroit Company and becomes president of that concern, though Mr. Thomas still remains a dominant figure in the organization. The product will also continue to be marketed by the Buffalo house, which has already con-

HUGH CHALMERS

Newly Elected President of the  
E. R. Thomas Detroit Co.

tracted for the entire season's output of the Detroit factory. In taking active hold in his new connection on December 1, Mr. Chalmers will bring to bear his wide knowledge of manufacturing and selling methods which he was instrumental in developing while with the Dayton concern, which is generally conceded to have the best selling force in the world. The other officers of the Thomas Detroit Company are H. E. Coffin, who is at present in Europe attending the London and Paris shows, F. O. Bezner, J. J. Brady, and R. D. Chapin. The output is to be greatly increased over that of the past season.

INFORMATION FOR AUTO USERS

**Smith Speed Indicators.**—For a number of years S. Smith & Son, Ltd., London, have devoted considerable attention to the development of speed and distance recording instruments, as well as electric communicators and auto clocks. The leader of their line is the Smith Speed Indicator, which has been for the past several years

find their way into every repair shop. On this wise there are no levers, pins or wheels and no complicated mechanism—in fact, no more parts than the ordinary stationary vise. The material employed consists of a blending of the best iron and steel, this mixture making very tough castings and adding materially to the life of the vise—

SMITH SPEED INDICATOR AND ITS CONVENIENT DIALS.

the leading article of its kind in Europe, as is evidenced by the fact that practically every crowned head on the Continent, as well as the king of England, are users of these instruments. In design the Smith Speed Indicator differs radically from the usual American device. It operates on the principle of centrifugal force, a horizontal governor being rotated against a spring, three springs in all being employed—a weak one for low speeds and two heavier ones which come into action successively as the speed increases, thus making the instrument very accurate, as well as avoiding the necessity of cramping the dial at one side. The marking of the dials is done by hand, according to the indication of the pointer at known speeds, and the dial of each instrument differs slightly to compensate for the variation of the springs. The length of the dial circle is 8 1-2 inches, as compared with the usual semicircular marking, so that the reading is very clear.

**Rock Island Vises.**—The art of doing one thing well aptly describes the achievement represented by the line of vises turned out by the Rock Island Tool Company, Rock Island, Ill. They are made in a great variety of patterns, including several especially adapted to the needs of the au-

SELF-LOCKING ROCK ISLAND VISE.

tomobile repair shop. An automatic self-locking swivel type is specialized by these makers, and its unique feature of locking in any position set, by merely tightening the jaws, is something that will commend it highly to mechanics who have to contend with the numerous unusual jobs that

in fact, the makers are so confident of the high grade of the Rock Island vises that they will immediately replace any defective parts gratis, also paying return charges. A New York office, in charge of Wm. N. Briggs, has been opened in the Electrical Exchange building, 136 Liberty street.

**Marvel Carbureter.**—Being unable to secure ample space at the Coliseum, the Marvel Manufacturing Company, Indianapolis, Ind., makers of the Marvel carbureter, will hold an exhibition of their own at the Southern hotel during the course of the Chicago show. In the construction of the Marvel carbureters, a sectional elevation of one of the float types being shown by the accompanying sketch, the makers have given careful consideration to the matter of materials. In the body only the best grade of red brass is used, while the gasoline needle and float valve bearings are made of the finest rolled Tobin bronze. In its construction the Marvel embodies many exclusive features, such as the universal gasoline connection, which facilitates its mounting on any car without the necessity of making alterations; ease of adjusting the float or float valve, removing the bowl or draining the residue from it, all of which can be done without changing the adjustment of the carbureter in any way. An annular type of float is employed and by combining the short neck of the carbureter and the inside union connection, the designer has gained a powerful leverage with a very short fulcrum, thus preventing flooding and bounding. An equalizing spring has also been added to the float needle, which gives a floating balance and an ease of movement which prevents any jar arising from sudden movements of the float. For cleaning, it is only necessary to remove the bowl and loosen one adjusting screw to release the entire float valve, needle and its accessories without disturbing their adjustment.

**Sireno.**—This is the title of a new siren signalling device which is being placed on the market by the Sireno Company, 39-41 Cortlandt street, New York. The external appearance of the instrument is shown by the accompanying illustration. The sound is produced by the familiar principle of centrifugal force, air being drawn through the front casing and expelled at the side openings, the current being generated by a rapidly revolving turbine driven by an electric motor. To operate, it is only necessary to push a button, the tone being regulated by the length of time the contact is made. It can be easily installed on a car, as it is only necessary to attach the instrument and connect it with the ignition battery. It

SIRENO (ELECTRIC) SIREN.

operates on a current consumption of three amperes and may be used in connection with a battery of six dry cells. It is made of polished brass, but can be supplied in any finish or plating to correspond with the other fittings of a car.

**Beach Auto Vest.**—This is a garment new to the automobile trade which is just being placed on the market by William W. Brown, Worcester, Mass., who is the sole owner of all machinery, patents and rights for the manufacture of the well-known "Beach" cloth, jackets and vests. The cloth is knit by a peculiar stitch that does not ravel or rip, and the vests are made with a heavy wool fleece lining. The cloth is elastic without being stretchy and in wear the garment conforms closely to the shape of the body. If soiled, the Beach

CROSS-SECTION ELEVATION OF THE MARVEL CARBURETER.

vests can be washed as often as desired without shrinking, something that can be said of very few knitted garments. The material is a hard-twisted double yarn, which gives long wear, and it is so closely

THE BEACH WARM-BACK VEST.

knitted as to be absolutely wind-proof. It is made with large pockets, the lower ones being lined with canvas, buttoning at the top with a snap, and adapting them for carrying spark plugs, coppers, or other small articles. It is made in both sleeve and sleeveless styles.

**Reversible Auto Tags.**—Owing to the perversity of some legislatures, State lines have become *real lines* to the autoist, who must see that his credentials are in the proper shape before driving his car over

REVERSIBLE AUTOMOBILE TAG.

the imaginary boundaries that mark the limits of jurisdiction of the different State authorities. To make the lot of the autoist easy where markers are concerned, H. E.

Asbury, Oak Lane, Philadelphia, is placing on the market the Asbury reversible tag, made to carry two different State numbers. In place of the usual flimsy fastenings, the holder is a permanent fixture solidly bolted to the car. The tag itself swings in brass bearings on a japanned steel back rod, to which are riveted two brass arms. After passing through two States it is only necessary to take out a single cotter pin with the fingers, swing open the top lever and put in a new tag, good for two more States, thus obviating the necessity of having the car plastered with hangers, or fastening them on temporarily as a makeshift, which not infrequently leads to a fine due to the loss of the tag.

**Crown Soft Oil Soap.**—The Crown Soap Company, Syracuse, N. Y., make a specialty of the production of genuine English oil soap, which is manufactured after a secret process known to but few. This company employs chemists who have been engaged in making this soap for more than thirty years past in England, where the secret of the process has been handed down from father to son in succeeding generations. Its chief use is as a preservative of highly finished surfaces and it has the quality of preserving varnish as long as it is used. It is equally valuable for removing grease from any surface and makes an excellent household and garage soap as well. It is an absolutely neutral soap of purely vegetable origin and thus contains no free alkali, which adapts its use on any highly polished surface, even such as that of a piano. Crown Metal Polish, made by the same firm, is an effective cleaner adapted for use on all metals, and which the makers claim does the work better and quicker, in addition to going further than any other compound of the kind on the market.

**The American Speedometer.**—One of the leading models included in the line of the Stewart & Clark Manufacturing Company, 502 Diversey Boulevard, Chicago, for the season of 1908, will be the American speedometer, which is the lowest-priced instrument of this kind ever turned out. There has long been a demand for a high-grade speedometer and mileage recorder at a popular price and there is little doubt that the makers are

justified in believing that the American at \$25 will fill all requirements. In bringing out this instrument, it has not been found necessary to curtail its size, the quality of the material entering into it, or the grade of workmanship employed on it. It has a full four-inch dial and is equipped with the same style of 10,000-mile odometer, barring the trip recorder, that forms a part of the Stewart speedometer. According to the manufacturers, the use of a simpler mechanism than that employed in the high-speed instruments, yet one which is positively accurate at all speeds up to 50 miles an hour, together with a new di-

THE NEW AMERICAN SPEEDOMETER.

rect flexible shaft attachment, makes it possible to supply this instrument at the very low price mentioned. Both the Stewart and the American speedometers are exclusively equipped with the patent Stewart swivel joint, the use of which permits of making the flexible shaft 18 inches shorter, and also allows it to be carried straight back along the frame to the dash without passing under or through springs without the right-angled bend usually necessary.

NEW YORK—THURSDAY, DECEMBER 5, 1907—CHICAGO

No. 23

## CHICAGO'S SHOW TELLS A SUBSTANTIAL STORY

### Supplies a Sum Total of Present Growth of a Great Industry and Gives to the Commercial Vehicle Its Distinct Place

By A. G. BATCHELDER.

CHICAGO, Dec. 5.—In a city where standards in great degree are measured by bigness, it seems perfectly logical that the most extensive and thoroughly comprehensive exhibition of automobiles ever held in this country—or abroad—should have a Middle West setting. There is no Grand Palais, nor an Olympia, in the vast overgrown town on Lake Michigan's shore, but in utilizing the Coliseum, filling the First Regiment Armory, and, finally, locating the commercial vehicles blocks away in the Seventh Regiment Armory, the idea of hugeness is accentuated and brought home with added force. Chicago may glory in the fact that it has the biggest display of automobiles ever assembled in a show, and, therefore, the National Association of Automobile Manufacturers may take pride in the housing of the Licensed and the Independent, and those who keep aloof from association connections, either of their own free will and accord or because they are not yet wanted. All that is allied to automobile construction, mostly those concerns belonging to the Motor and Accessory Manufacturers, Inc., swell appreciably and necessarily the sum total of a substantial, great and permanent industry.

Plainly apparent is the tone of renewed optimism and unquestionably missing is that atmosphere of gloom which permeated the first New York show, unfortunate enough to come during the low-water mark of the Wall Street disturbance and continuing in lesser form during the Garden event. Out here there is a natural desire to be free from "Eastern domination"—as it is designated—and while the money mart of the metropolis has its weight throughout the entire country, its influence weakens perceptibly as it travels west; and just now there is a feeling of resentment in antagonizing it from this bustling and self-conscious town. Here the banks are known to have on hand untold millions in gold and silver and greenbacks, but they intend to have little of it go eastward until the money kings of New York loosen up, which, is the belief, will come with very little delay.

There is, however, hunks of optimism at the morning after-breakfast assembling in the lobby of the capacious Auditorium Annex, and, let it be told also, there is less of that

epidemic of late wine-buying in the flashy Pompeian room which has characterized previous shows. As the automobile "game" resolves itself into the automobile industry, there disappears and fades away, one after another, that class of salesmen who are addicted to lengthy expense accounts for "entertaining" of a recklessly generous nature.

Automobiles, with a few decreasing exceptions, are now being sold on merit alone, which brings us to remark that the weaklings are going to be weeded out somewhat precipitately during the next few months. Some good concerns with reliable products are being caught in the financial squeeze, but it is reasonable to prophesy that their affairs will be readjusted when the present temporary transition period has had its innings.

One keynote of the situation was struck by Thomas B. Jeffery when he said to a Chicago reporter, insistent upon getting something from the hard-headed, discerning, veteran manufacturer: "There is not sufficient question about the future of the automobile to warrant discussion. The

automobile is just as much indicative of the progress of the present age as the trolley car, and is bound to be just as permanent. Our staple demand is for autos for utility purposes."

As the week wears on the commanding figures in the industry are appearing. Charles Clifton, the keen-sighted president of the Association of Licensed Automobile Manufacturers, reached the scene Tuesday morning, preceded the day before by Milton J. Budlong, the new general manager, whose recent accession to office has met with much approval from the Seldenites. Thomas Henderson, president of the N. A. A. M., was early in evidence; Benjamin Briscoe, chairman of the committee on management of the American Motor Car Manufacturers' Association, appeared without Alfred Reeves, the general manager, who is looking at the European shows. A roll-call now would bring a response of "Here!" from representatives of nearly every concern identified in one way or another with the industry; and many are in Chicago for the purpose of attending various sorts of conferences and meetings, the results of which may have great import and change the complexion of matters somewhat chaotic at this writing.

GODDESS OF SPEED.

PLEASING TRIPLE EFFECT IN THE COLISEUM.

After the autos are sold there follow some problems for the owners, and that is why a national association of users, subdivided into State bodies and local clubs, is a valuable adjunct, not only for the owner but for the maker, who must realize that if automobiling is not made agreeable and convenient there will be less demand for his product. This is where the American Automobile Association fits into the grand scheme, to work for a national registration measure and uniform State laws, urge the improvement of the roads, supply touring information, and control racing. In William H. Hotchkiss, of Buffalo, the A. A. A. has a worthy leader, through whose efforts the membership has been increased from 8,000 to nearly 20,000 in the past nine months. The greater the number the greater will be the power of the A. A. A. and its ability to accomplish things. President Hotchkiss arrived this morning, to be present at several sessions, the news of which when announced may be worth the attention of all.

#### Ornamental Effects Much Admired.

Appreciation of the show decorations is outspoken on the part of the visitors, even where the latter had the advantage of being in a position to make comparisons with previous efforts in this direction. But these decorations were the despair of photographers, who were, accordingly, not enthusiastic over the extra efforts that Manager Miles had put forth to make the present show surpass anything of the kind he has done before, and that is saying a great deal, as the Chicago show has become famous for the completeness of its preparations. The most noticeable fact about the decorations, however, is that everything is in keeping—every part of the decorative scheme blends harmoniously into one attractive whole, and this, moreover, forms a most appropriate setting for the cars without in any way detracting the visitor's attention from the chief object in view: the automobile and its numerous accessories. One does not become lost in admiration of the gorgeous setting, and in doing so miss the purpose for which it is intended.

Figures fail to adequately express the extent of the task of installing such a great amount of material, and the fact that so many thousand pounds of stuff and so many thousand yards of carpet are necessary to its completion means but little to the average man, but when he has made the rounds of the three buildings he begins to have some idea of the vastness of the undertaking. Praise was forthcoming from every quarter, so that in addition to the satisfaction which accrues from the successful completion of such an achievement, Manager Miles and assistants were not long left in doubt as to the reception their work received. This was particularly the case where the oil paintings by Maratta were concerned—a feat in the decoration of a purely industrial exhibition never before attempted. In addition to the huge canvases that were suspended from the gallery railings, and which served to hide the ugliness of that part of the Coliseum's dingy ironwork in a more effective manner than was hitherto thought possible, every exhibit had its own individual background.

#### Three Separate Shows in All.

"Let's go over and see the other show" is the way the average visitor to the Coliseum expresses himself regarding a visit to the First Regiment Armory, which is not considered in any way as an annex, or an overflow from the main body of the show, but as a complete exhibition in itself. And such it is, for with its dozens of exhibits of complete cars and scores of accessory booths encircling the surrounding gallery, it is a complete show in itself of a size that many a large American city, outside of New York or Chicago, would be proud to boast. But the famous "pneumonia alley" of the past two years is no more. Instead of building a wooden chute through which the attendance at one building could shunt itself to the other, the wide alley itself has been roofed over with canvas and lighted, separate entrances and exits being

provided at each building for the incoming and outgoing crowds. This expedient eliminated much of the confusion attendant upon the two colliding streams of humanity that characterized the wooden chute, but the practice of requiring tickets at the entrance to each occasionally brought about more or less delay and annoyance. But more than ever before is it really a case of seeing two shows for one admission, for the First Regiment Armory exhibits are fully as complete in themselves, and quite as distinctive in a way for that matter, as those at the Seventh Regiment Armory.

This, despite the fact that the Coliseum's available floor space has been stretched to the extent of accommodating fifteen additional exhibits of cars and twenty-five additional exhibits of accessories, over and above what it has been considered capable of housing in former years. This has been accomplished by utilizing a portion of the building that, under ordinary circumstances, would never have been considered as fit for the purpose, but which under the high-pressure demand for space has been converted into as attractive a part of the show as any other. This is the basement of the Coliseum annex, and, in striking contrast with the conditions prevailing below stairs in other years, the visitor does not find it essential to his comfort to get back to the main floor again as quickly as he can. In a measure, this basement overflow is also somewhat of a show in itself, for ranged down the center of the several thousand square feet of floor space thus made available is a showing of complete cars, many of them of ambitious size and attainments, and as most of them are new, well worth a little study where design and construction are concerned. Flanking them on every side, in the manner inseparably associated with all automobile shows, are the accessory exhibits ranged about the wall booths, and here again there are quite a number of new things to take the attention.

#### Trucks Are Thoroughly Businesslike.

It seems quite fitting and appropriate that the first thing to greet one on entering the Seventh Regiment Armory is a strong flavor reminiscent of the horse. It strikes the nostrils immediately on opening the single heavy door which bears no invitation to enter, and it is so all-pervading that it immediately gives the impression of the horse just having been led out of one door of his life-long abode to make room for the power-driven truck to come in at the other. There is another air about the Seventh Regiment Armory, once the visitor finds himself fairly inside of it, and it is one that does not strike him in the least unpleasantly. It is the quiet, businesslike air that is over everything. In fostering this first annual show for the commercial vehicle alone, the management fully realized that the man who is interested in automobile transportation wishes to learn all he can about it with the least outlay of time, or necessity for running around, and they have accordingly provided the opportunity. Tickets have only been issued upon request, apart from those special invitations sent out by exhibitors and the management to interested parties, so that while there is always an interested audience in the old horse-mart, but a sprinkling of the crowd that fills the aisles and the galleries of the Coliseum and the First Regiment Armory finds its way over to the commercial show.

But once inside he is amply repaid for the trouble, for the result of this first attempt at bringing together those makers who are now bending their efforts toward the production of what is destined to form a great part of all the automobiles turned out has more than exceeded the fondest anticipations of the promoters. One hears nothing but talk of ton-miles, overload capacities, fuel and oil consumption, cost of tire maintenance, and reliability percentage. "Investing" is the keynote of all conversation between sellers and prospective buyers.

An outbreak of fire in the Seventh Regiment Armory caused temporary excitement Tuesday, but the flames were extinguished with damage to decorations only.

IN THE SEVENTH REGIMENT ARMORY THE COMMERCIAL VEHICLE HELD ITS INITIAL EXCLUSIVE EXPOSITION.

## THE FIRST AMERICAN COMMERCIAL VEHICLE EXHIBITION

By HARRY W. PERRY.

NEVER before has there been such a good opportunity to display motor trucks and delivery wagons as is offered by the first annual exhibition of Commercial Motor Vehicles that opened this afternoon at 2 o'clock in the old Tattersall's building, famous in Chicago history for its horse shows, prize fights and bicycle races but now occupied as an armory and drill hall by the Seventh Illinois Regiment. In exchange for the low, narrow subterranean passages of the basement of Madison Square Garden and the incongruous setting of Grand Central Palace and the Coliseum Annex, the builders of business wagons have this winter in Chicago been given advantages for displaying their products that are fully equal to the best that the pleasure car makers enjoy.

In spaciousness Tattersall's compares very favorably with Madison Square Garden, having a high arched roof and open floor only a little smaller in dimensions than New York's

famous show place. The decorations, although less elaborate than those in the Coliseum, are more complete than could reasonably be expected and are in good keeping with the character of the event. Broad strips of alternating yellow and blue cloth are draped under the roof to conceal the steel arches and hung along the balustrade of the gallery. The floor of each exhibition space is covered with a green rug having a red border, and a band does its best to dispel the quiet that reigns while the exhibits and exhibitors await the coming of visitors. Certainly the show management has done its part toward providing a good commercial vehicle show—if the event is not the success that it should be the fact will have to be ascribed to failure of the manufacturers to make the most of the first real good chance they have ever had properly to show their vehicles under cover, or to lack of interest on the part of possible purchasers.

Several large empty spaces due to withdrawals at the last

WHERE THE RAPID AND POPE COMMERCIAL VEHICLES ARE DISPLAYED, WITH TASTE, AND IN PROFUSION.

THE ONE-TON AIR-COOLED FRANKLIN WITH STAKE BODY.

HERE THE FREIGHT CARRIERS LOOK BIG AND POWERFUL

minute by exhibitors who had engaged space indicated on the opening day that the efforts of the management had not been met with the most generous reciprocal spirit. Present financial conditions are largely responsible for the withdrawals, while the delay of shipments by railroad account for some of the empty spaces. Despite the absentees, it is a good show and ought to go down in history as superior to the early automobile shows both in general tone and in sane practice in design and construction.

Although admission is free by card, the attendance on this first afternoon and night was almost nil, probably on account of bad weather and the attraction of the simultaneous show of pleasure cars and accessories in the Coliseum two blocks to the east on Wabash avenue. During the coming week there is little doubt that out-of-town agents will drift over to inspect the commercials with a view to adding some make of delivery wagons and trucks to their lines, while business men of the city and farmers in attendance at the live stock show, which will also open during the next two weeks, will visit the show in the daytime.

To summarize the show briefly, it may be stated that there are nineteen exhibitors of commercial vehicles whose displays were in place when the show opened, and of these four makes are electric vehicles and the rest gasoline. Eleven makes were not shown at either of the New York shows and at least two makes have never been exhibited in public anywhere before in America. One of these is the Weeks, just completed before the show by the newly organized Weeks Commercial Vehicle Company, of Chicago, and the other the Safir, just imported from Switzerland by the Commercial Motor Car Company of New York, after it had won a gold medal in the commercial vehicle trials in Berlin. Besides the displays of work vehicles, there

are several exhibits of pleasure cars that could not be accommodated in the Coliseum or the First Regiment Armory on Michigan avenue. These are the Halladay seven-passenger touring car built by the Streator Motor Car Company, of Streator, Ill.; the Colt runabout made by the Colt Runabout Company, of New York, and the Pontiac buggies, built by the Pontiac Spring and Wagon Works, of Pontiac, Mich. There are eight absentees, two of whom are new makers—the Worth Motor Vehicle Company and Gifford-Pettit Manufacturing Company—while the General Vehicle Company, the White Company, Logan Construction Company, and Alden Sampson Manufacturing Company are reported to have decided not to make displays. The Buckeye Manufacturing Company (Lambert) and the Continental Motor Car Company are also notably absent. The withdrawal of the Sampson train and the White cars is unfortunate, as their absence detracts from the representative character of the show, which now has no representative of the mixed gas-oil-electric or the steam classes.

The predominance of gasoline vehicles is apparent, although the four exhibitors of electrics make a strong showing, the Studebaker Automobile Company showing the largest number of machines of any single exhibitor in the building—seven, as follows: An 800-pound laundry wagon in yellow, a 1,000-pound chassis in lead, a 2,500-pound express wagon with top and curtains, painted blue, a sixteen-passenger omnibus in dark green, a 4,000-pound stake truck in green, a 7,000-pound stake truck in bright red, and a 10,000-pound stake truck in blue. Of these the first four were at the Licensed Show in New York. The Studebaker company is bringing out two new trucks to be ready in February, one of three tons capacity and the other of four tons. The Pope Motor Car Company shows three Pope-Waverley electrics—an open body express wagon in dark green, a

MITCHELL DISPLAY INCLUDED BOTH DELIVERY AND TRUCK.

COLT FOUND SPACE IN THE COMMERCIAL VEHICLE SHOW.

MAXWELL EXHIBIT INCLUDED A CASE OF VALUABLE TROPHIES WON.

closed light delivery wagon, and a 1,500-pound express wagon with top and side curtains, the body painted bright green and the running gear red. Three electrics are also shown by the Pittsburg Motor Vehicle Company, which has not exhibited at shows during the last two years. Two of these are 750-pound closed delivery wagons and the other a 1,500-pound covered delivery wagon—one of a lot of nine that have just been completed by the factory.

All of the foregoing electric vehicles may be said to be of the conventional or standard type, the lighter wagons being driven by a single motor hung from the frame in front of the rear axle and the larger ones by double motors of General Electric, Westinghouse or Waverley manufacture, also hung from the frame and driving by double side chains to sprocket drums on the rear wheels. Batteries are underslung between the axles, and the front wheels only are employed for steering, while only the rear wheels drive. Except in the Pittsburg vehicles, the running gears are made with channel steel frames and bodies are interchangeable, so that any style desired can be fitted according to the requirements of the service. In the Pittsburg wagons the frames are made a part of the body, really constituting the sills, whereby it is claimed that a material reduction of weight in proportion to carrying capacity and mileage is secured.

Of an entirely different type are the vehicles of the Couple-Gear Freight Wheel Company, of Grand Rapids, Mich., which has never exhibited at Eastern shows. These have the motors inside the wheels, which are made of two disks of pressed steel. One five-ton truck is shown in which all four wheels are drivers and all four are used for steering. They are fitted with the only set of sectional wood tires in the show. It may also be observed that the Couple-Gear trucks are the only vehicles on exhibition regularly equipped with steel wheels, although pressed steel

AN EFFECTIVE CORNER OF THE COLUMBIA EXHIBIT.

QUIVER WHERE ALL OF THE GREAT ARROWS WERE HELD.

wheels are shown in the gallery by the Indestructible Steel Wheel Company.

In the gasoline vehicles there is wide diversity of practice. Extensive application has been made of double opposed engines, of two-cycle operation, air cooling, friction drive and planetary transmission with the object of making the vehicles as simple and "fool-proof" as possible, it being well understood that the great majority of delivery wagon and truck drivers in America are recruited from the ranks of horse drivers, who cannot be expected to have a special training in mechanics. Thus there are five air-cooled makes of trucks—the Knox, which is shown in two models, a 1 1-2-ton open express wagon with double opposed air-cooled engine placed lengthwise underneath and driving through planetary gears to differential countershaft and side chains, and the newest three-ton model, having a vertical four-cylinder engine in front under the seat, sliding gear transmission with shaft drive to countershaft; the Frayer-Miller, shown in 5,000-pound stake and 5,000-pound express models, fitted with four-cylinder vertical engine in front, whose special feature is cooling by means of a forced draft induced by a blower driven by the engine; the Sayers & Scovill, built in Cincinnati and having also a vertical four-cylinder engine under the driver's seat, transmitting through sliding gear change-speed to countershaft; the Franklin one-ton stake truck, with four-cylinder vertical engine, and finally the new Weeks 1,000-pound delivery wagon fitted with a double opposed motor placed crosswise above the front axle under the footboard.

The Weeks car also belongs in the class of friction-drive machines, of which the Meiselbach one-ton chassis and two-ton beer wagon built by the A. D. Meiselbach Motor Wagon Company, of North Milwaukee, and the Plymouth two-ton chassis shown by the Commercial Motor Truck Company, are also ex-

THE DISPLAY OF APPERSONS WAS PROFUSE AND ATTRACTIVE.

amples. The Plymouth and Weeks have transmissions quite similar in appearance, comprising two parallel friction disks driven by the engine and two friction wheels between them mounted slidably on a cross shaft, from the outer ends of which chains drive to the rear wheels. In the Meiselbach, however, the continuation of the engine shaft carries two fiber cones, either of which can be forced into simultaneous contact with the beveled faces of two heavy disks mounted on jack shafts, one cone when in contact giving forward speed and the other reverse. This transmission gives no speed variations, the engine being depended upon for this, but in the other makes the friction wheels can be shifted on their shafts across the disk faces to vary speed.

Examples of two-cycle engines are found in the Weeks, Coppock and Reliance cars. Whereas the Weeks is an opposed engine set crosswise, the Coppock is a twin cylinder motor set vertically in front under the seat and fitted with removable copper

Car Company of New York, which imported it from Switzerland just in time to reach the show. It recently competed in the commercial vehicle trials in Berlin and won a gold medal. It has a Saurer engine and is especially notable for two refinements that are rarely found upon even high-priced foreign touring cars. One is a self-starting device, which utilizes compressed air from a tank into which it is forced by a small compressor driven by the engine and admitted to the cylinders on the working stroke of each piston by a special distributor. The other is a device for utilizing the engine as a brake. By means of a small lever on the steering wheel the camshaft can be advanced 90 degrees in order to hold the exhaust valves closed on the scavenging stroke, thereby obtaining the resistance of compression on every up stroke of the pistons. These features are fitted to order.

The only one-cylinder engine is found in the smallest work car in the show—the Brush 500-pound delivery wagon. This has

A SAMPLE OF THE AUTOMOBILE ART WHICH DECORATES THE COLISEUM AND ADDS MUCH TO ITS EFFECTIVENESS.

water jackets, and the Reliance is of two, three and four cylinders, according to the capacity of the vehicle, and is also set vertically in front. The Reliance Motor Vehicle Company shows a two-ton express wagon with two-cylinder engine, a three-ton chassis with three-cylinder engine, and a four-ton stake truck with four-cylinder engine.

Double opposed water-cooled engines are employed in the Meiselbach and Rapid trucks, the former make having the engine set across the frame at the front and the latter having it placed lengthwise in the middle of the frame. Two machines are shown by the Rapid Motor Vehicle Company, of Pontiac, Mich. One is a truck chassis and the other a twelve-passenger stage that completed the 600-mile reliability test held this week by the Chicago Motor Club within the schedule time for touring cars.

The more conventional type of vertical four-cylinder water-cooled motor is seen in the American five-ton truck shown by the American Motor Truck Company of Lockport, N. Y.; the Plymouth, which is fitted with a Continental engine; the Mitchell, shown in express wagon and closed delivery types by the Mitchell Motor Car Company; in one model by the Reliance Company, and also in the Safr.

The Safr is the only foreign machine upon exhibition. It is shown in a four to five-ton model by the Commercial Motor

a canvas-covered body mounted on the 6-horsepower runabout chassis. The engine sets upright at the front under a hood.

The Thomas taximeter cab, which is shown in the chassis and also complete with landaulet body equipped with a Kosmos taximeter, has a vertical four-cylinder water-cooled motor, but it departs from the conventional in having all the cylinders together with their jackets made in one casting, a further peculiarity being the enclosing of the exhaust and intake pipes in the jacket.

Very good displays of solid tires for all purposes are made in the gallery by the Diamond Rubber Company, Hartford Rubber Works Company, Morgan & Wright, Goodyear Tire & Rubber Company and Firestone Tire & Rubber Company. The Timken Roller Bearing Axle Company shows a line of massive hubs and front I beam and forged solid square rear axles, all equipped with its roller bearings. Pressed steel wheels for both light and heavy vehicles are exhibited by the Indestructible Steel Wheel Company. Exhibits of the Automobile Utilities Company, Carter Chapman & Co., Atlas Manufacturing Company and National Battery Company were not in place up to the close of the show on Saturday night. Shipments were probably delayed in other cases as well as in the case of the Automobile Utilities Company.

## CARS FOR 1908 FIRST SHOWN IN A WESTERN SETTING

By CHARLES B. HAYWARD.

**T**HOUGH it would appear at first sight that two such shows as the East fosters would be sufficient to bring out practically everything novel that the industry had to offer, and particularly this year, when Western makers were almost as a unit in taking space at New York, there has never been a time when Chicago's opening night failed to reveal a gathering of new claimants for attention, as well as a number of makers who confined their activities in this direction to the West. In previous years it was usually found to be the case that many of these of the former class

TWO-CYLINDER 24-HORSEPOWER AUBURN TOURING CAR.

were of the "here to-day and gone to-morrow" kind, and no one ever expected to hear anything further of them after the end of the show, in which they were seldom disappointed.

This is something in which the first-nighter at the Coliseum found a rather striking contrast to former years, for almost without exception, there is an air of substantial solidity about the new cars which shows that they are not in the experimental class and their makers are not here merely for this show alone. Another thing to strike the observer's attention is that the day when the Western maker has dropped the pastime of producing impossible freaks is likewise practically a thing of the past, although it must be added that this is something which has died hard and has hung on to a greater extent here in the Middle West than it did in New York. Naturally nothing of a revolutionary nature was to be looked for, and it is just in lacking objectionable features of this nature that most of the cars in question reveal their worth, as well as the standing of their makers.

**Aerocar.**—This is a line that scarcely needs any introduction to the automobile public, and if the work of reorganizing the company which is now known as the Aerocar Motor Company, Detroit, could have been expedited somewhat, the concern's new models for 1908 would have been exhibited at New York. Both air and water-cooled cars will be specialized as heretofore and practically all of the distinctive features which have become familiar on the Aerocar during the past two years or more have been retained intact. For instance, the 4x4-inch, valves-in-the-head air-cooled motor will still be a feature of the 20-horsepower car of that type, while the special design of water-cooled motor which was brought out for the first time by the Aerocar Company a year ago will be retained on the water-cooled car, which is an unusually attractive and serviceable looking machine. Both the air and water-cooled types will be almost entirely the exclusive product of the home factory, accessories and

outside parts wherever used being of the highest grade throughout. In both cases, a standard pressed-steel frame, long semi-elliptic suspension, seamless steel tubular front and rear axle, ball-bearing steering knuckles, multiple-disk clutch and sliding change-speed gear with shaft drive, are familiar items of construction which will be retained as features of the 1908 model. Both touring cars and roadsters are listed in both the air and water types.

**Auburn.**—In bringing out their new models for the season of 1908, the Auburn Automobile Works, Auburn, Ind., who have been building popular-priced cars ever since 1902, have fully realized that even the man who buys a low-priced car wants it to look like the standard high-priced production, and he wants this just as much as he does good materials and reliability. In consequence, they have devoted their energies to the production of a car which is representative of the highest standards of its particular type of construction, beside being a machine of most attractive appearance. The double-opposed motor measures 5 1-4 by 5 inches and is rated at 24-horsepower. A planetary change-speed gear is employed with shaft drive, control being by means of pedals, except on the high speed. The foundation of the chassis consists of a standard type of pressed-steel frame, supported on full-elliptic springs on the rear and the half-elliptic type forward. The wheelbase is 100 inches, and the wheels are 32 by 3 1-2-inch, Goodrich quick detachable tires forming the standard equipment. In fact, throughout its entire makeup only the highest grade accessories, such as the Hill Precision oiler, Schebler carbureter, Raymond brakes and the like, have been employed. As a five-passenger touring car, the Model G Auburn lists at \$1,350, with full equipment, Model H being the same car with a special equipment of top, gas lamps, storage battery, four-inch Goodrich tires and other fittings, on which a special price is quoted. As a runabout, it is known as Model K, and lists at \$1,250.

**Aurora.**—Long experience in the building of automobiles of the popular-priced type has confirmed the makers of the Aurora, The Aurora Motor Works, Aurora, Ill., in the opinion that for the service of the average man there is nothing to exceed the two-cylinder, horizontal type of motor. Accordingly, they provide their 20-horsepower runabout with a 4 1-2 by 5-inch motor, but it is placed under the bonnet forward with the gear-set, particular pains having been taken to make every part of the mechanism perfectly accessible. A planetary type of change-speed gear is employed, the final drive being by shaft, everything about the car being of the strongest and most durable construction to fit it for the use of the man who expects his car to run 365 days in the year with a minimum amount of expense and trouble. The

LAUTH-JUERGENS 50-H.P. "STRAIGHT CYLINDER" TYPE.

LATEST DIAMOND T RUNABOUT, MADE IN CHICAGO.

frame is of angle steel, well braced, and is supported on long semi-elliptic springs forward and a platform suspension in the rear, and these in turn are carried on a tubular front axle and an extremely simple and efficient rear axle driving-unit. The wheelbase is 80 inches and the tread standard, tire equipment consisting of 32 by 3-inch clincher or Goodyear quick detachable tires. In complete running order the car lists \$775.

**Bugmobile.**—Despite the title of this latest comer to the small car class, which is suggestive of a buggy type of automobile, this new car, which is the product of the Bugmobile Company, 208 Wabash avenue, Chicago, embodies many features of construction patterned after far higher-priced standards. For instance, it has an angle steel frame on which the entire power-plant and transmission are centrally located. A two-cylinder horizontal-opposed air-cooled motor of the four-cycle type is employed, in connection with a special chain type of change-speed gear, with final drive to the rear wheels from a countershaft by means of steel cables. In complete running order the car sells for \$750.

**C-F.**—This is the title of a new car which is the production of the Cornish-Friedberg Motor Car Company, 1233 Michigan avenue, Chicago. Though brought out during the past summer, this is the first time it makes its bow at a show stand and it does not require much study to come to the conclusion that its builders have not attempted anything radical or revolutionary, but have adhered closely to well recognized engineering practice, so that the new C-F car is really a standard production throughout. The idea of its builders has been to meet the requirements of that large class of buyers usually included under the generic title of the "average automobilist," and have accordingly concentrated far more in their 35-horsepower car at \$2,250, than would have been thought possible to offer at this figure but a year or two ago. Its 35-horsepower motor is of the standard four-cylinder, four-cycle, water-cooled type, developing more than its normal rating at a comparatively low speed. A multiple disk-clutch and selective type of change-speed

PUNGS-FINCH 45-HORSEPOWER 7-PASSENGER CAR.

gear, with final drive by shaft to a floating rear axle, constitute the essentials of the transmission. As a five-passenger touring car, it has a 14-inch wheelbase and tips the scales at 2,300 pounds.

**Chicago Motor Buggy.**—As its name indicates, this is a machine of the now extremely popular high-wheeled type, which is the product of the Black Manufacturing Company, 124-128 East Ohio street, Chicago, but its makers have determined to bring a reliable car of this kind within the reach of a far greater number of possible users than has been the case up to the present time. It has a two-cylinder horizontal, 12-horsepower, air-cooled motor, planetary change-speed gear and double side-chain drive, Diamond block chains being used between the countershaft and the rear wheels; high-tension ignition, Kingston carbureter, wheel steer, rear-wheel brakes, angle steel frame, bevel-gear differential and many other features of much higher-priced cars of the touring type, despite which the Chicago Motor Buggy is offered in three models ranging from \$375 to \$575 in complete running order.

**Duer.**—That the high-wheeled and solid-tired automobile is destined to be the popular car of general utility, no one can doubt for a moment. It is durable, light, speedy, easy to repair and able to travel anywhere a horse-drawn vehicle can go. In bringing out their car, the makers of the Duer, The Chicago Coach & Carriage Co., 1223-31 Michigan avenue, Chicago, have kept all these requirements before them. In consequence, the Duer is neither a made-over buggy nor an assemblage of miscellaneous parts; in short, it combines all the good qualities of the high-wheeled type of machine with many of those of the standard automobile. For instance, its two-cylinder, air-cooled, 12-horsepower motor is mounted under a bonnet forward and every part of it, as well as that of the change-speed gear, which is of the selective type giving two speeds ahead and reverse, is accessible in every part. The wheels are 44-inch front and 48-inch rear, running on Timken roller-bearing axles. Semi-elliptic springs are employed forward and full-elliptic in the rear, the tire equipment being 1 1-4-inch solids. The car is capable of a speed up to thirty miles an hour, and with full equipment, including top and curtain, it lists at \$750.

**Lauth-Juergens.**—This is one of the most powerful of the new comers to be seen at the show. It is made in two types, one with a straight cylinder and valves in the head, and the other, of the "T" head type, by the Lauth-Juergens Motor Car Company, Chicago. The former measures 5 by 6 inches and is a most powerful motor of its size, while the smaller motor of the oppositely-disposed valve type, measures 5 by 5 1-2 inches, and is rated at 45-50 horsepower. In both cases, the makers have devoted great pains to perfecting the details of the power-plant, so that upon closer observation the car is found to embody a great many distinctive features. For instance, the valves with their springs are assembled and are seated separately on the cylinder head, so as to be removable for cleaning or grinding, without disturbing any adjustment. The change-speed gear is out of special type, as is also true of the clutch; the former is of the selective, three-speed forward pattern, with but one moving member, giving the slow forward and reverse speeds. The intermediate and direct-drive pinions do not slide, being locked with a patented sliding jaw clutch, all speeds not in use at the time being locked; and it is also possible to effectively lock the gear-set at neutral. The complete clutch is composed of three parts, two of them being metal disks between which is placed a special fibre disk, having a large friction surface. Both the gear-set and clutch are so mounted that they may be removed for inspection or repair in a very short time. In other respects, the car closely follows recognized standards throughout. Final drive is by shaft to a

live rear axle, while the forward axle is a 2 1-2-inch solid forging of the "I"-beam type. The straight type motor forms the power-plant of the 50-horsepower Lauth-Juergens Tourist, which lists at \$2,800 with the usual standard equipment. It has a 118-inch wheelbase, and 36 by 4 1-2-inch tires.

**Lorraine.**—This newcomer is a Chicago product that is characterized by numerous features of merit from an engineering point of view, in addition to which it embodies several points of exclusive design, and is manufactured by The Lorraine Automobile Manufacturing Company. The Model L is a 50-55-horsepower four-cylinder car with a standard four-cycle, water-cooled motor. The cylinders measure 5 by 5 inches and are offset 1 1-4 inches, beside being provided with unusually long connecting rods, the dimensions of the latter being 12 inches. The oiling system is of the simple and efficient self-contained type, the gear pump being fixed to the lower end of a vertical shaft clutched at its upper end to the lower end of the commutator shaft. The distinguishing feature of the power-plant is the Hobbs-Renault self-starter, which is of the compressed air type and is situated between the clutch and the gear-set, air being stored in a tank and maintained automatically at a pressure of 60-80 pounds, so that the apparatus is always capable of

A POPULAR PRICE WESTERN TWO-CYLINDER RUNABOUT.

starting the motor from sixteen to twenty times. The pressure pump of the starter is also used for inflating the tires. A standard conical clutch is employed in connection with a sliding gear, an option being given on the progressive or selective type of operation. Hess-Bright ball-bearings are used throughout this essential. Another distinctive and meritorious feature of the Lorraine is the Hobbs elastic shaft, consisting of a series of spring-steel rods, concentrically arranged, one end being rigidly connected to the driving element, and the other to the driven element with an intervening clutch to carry the load on a rigid shaft when the torsion of the rods reaches a fixed limit. The wheelbase is 124 inches, and Goodrich detachable tires are employed on the 36 by 4 1-2-inch running gear. In the Models M and N Lorraine cars the specifications are practically identical, with the exception of the smaller motor rated at 25-30 horsepower and smaller tires, measuring 34 by 4 inches.

**Monarch.**—Although the name has been a familiar one for several years past, the Monarch car for 1908 is something entirely new, and it is quite evident at a glance that its creators, the Monarch Motor Car Company, Chicago Heights, Ill., have made a close study of the best there is in automobile design, both here and abroad, and have adopted features that have stood the test of time in thousands of cars in addition to embodying numerous special exclusive points of their own. The power plant and transmission are of the integral unit type, supported on a three-point suspension. The four-cylinder, four-cycle, water-cooled motor is rated at 40 horsepower, while the selective gear-set pro-

WATER-COOLED 40-HORSEPOWER AEROCAR.

vides three speeds forward and the usual reverse. In every line the motor follows the highest standard practice, for which the designer has shown by the many distinctive points of construction it reveals that it is an exceedingly well thought out piece of mechanism, which is produced in its entirety at the home factory. For instance, a vanadium steel crankshaft is a feature, as is also the Bosch high-tension magneto employed for ignition, not often found on a car listing at \$2,500 in complete running order. The same standard chassis is equipped as a two-passenger runabout and known as Model F, while as a five-passenger touring car it is called Model G. The wheelbase is 112 inches, while the tires are 36 by 4-inch Goodyear quick-detachable type on universal rims, this also being a feature not frequently found on popular priced cars.

**Oakland.**—This a new car from the hands of Allanson P. Brush, who has designed it for the Oakland Motor Car Company, of Pontiac, Mich., Mr. Brush being the vice-president and consulting engineer of the company. The motor is a two-cylinder vertical water-cooled type, measuring 4 1-2 by 5 inches and is equipped with a special counter-balancing device which entirely overcomes the great disadvantage of excessive vibration, otherwise a drawback of this type of motor. It is distinguished by an exceedingly simple type of carburetor with but one moving part, the air valve, which is also simple and fool-proof. Cooling is by thermo-syphon circulation through a tubular radiator. The change-speed gear is quite novel in that it is patterned after the planetary type, the brake bands, however, being replaced by self-contained clutches which run in oil inside the housing. Another quite distinctive feature is the use of a white ash frame in place of the usual pressed-steel construction. The car is rated at 20 horsepower, and has a 96-inch wheelbase. Either 30 or 32 by 3 1-2-inch wheels will be fitted, an option being given on Diamond, Continental, Firestone or Goodrich tires. In complete running order the five-passenger

A NEW ONE OF THE BUGGY TYPE.—STAVER MODEL D.

Oakland touring car hits the scales at 1,700 pounds, while the runabout weighs 100 pounds less.

**Pullman "Flyer."**—This is an entirely new line of cars which is being built and marketed by the Pullman Motor Car Company, 131-133 La Salle street, Chicago. While new in a sense, the Pullman "Flyer" is a composite of the best to be found in the automobile world to-day, for, as its makers state, the meritorious features of fifty of the world's best cars have been combined in it. The motor dimensions are 5 1-4 by 5 1-2 inches and its rating is 45-50 horsepower. Any further description of the power plant would simply be a repetition of those features that are generally recognized as representing the highest standard of design. The change-speed gear gives four forward speeds with a direct drive on the third, all the pinions and shafts being made of chrome nickel steel in an extremely high tensile strength, while the shafts are supported on five F. & S. annular ball bearings. A Bosch magneto of the high-tension type is a feature, the motor ignition being of the dual order, each system being entirely independent. The clutch is of the compression band type, and no less than five brakes are provided, one of them being an extremely powerful air-cooled transmission brake, operated by an emergency pedal. The car has numerous other distinctive features which it is impossible to detail here. Five models are listed, including a touring type, a "Speed car," a limousine, a special six-cylinder touring car and a special six-cylinder "Speed car," ranging in price from \$3,800 to \$5,000.

**Pungs-Finch.**—For 1908 the line turned out by Pungs-Finch Auto and Gas Engine Company, Detroit, will comprise three distinct models, all being equipped with a standard type of four-cylinder, four-cycle, water-cooled vertical motor. The smallest member of the 1908 Pungs-Finch family will be model F, a 24-horsepower, two-passenger roadster, listing at \$2,000, and this is naturally a car to which the builders will devote a great deal of their attention during the coming year, owing to the extent of the demand for vehicles of this type. It has a cone clutch, selective type of sliding change-speed gear and final drive by shaft. With a 108-inch wheelbase, it tips the scales at 1,950 pounds. The model H is a 35-horsepower car which incorporates several features not found on its smaller brother. For example, it has a multiple disk type of clutch, and while most of its remaining features are similar in type to the smaller car, they naturally embody many detailed refinements. As a five-passenger touring car the wheelbase is 110 inches and the weight all on 2,300 pounds. With the usual standard

equipment of tools, lamps, and the like, this car lists at \$2,500 in complete running order. The largest member of the line is a 45-horsepower four-cylinder car, practically all of the essential features of which are duplicated in the machine just described, but like the last named the big car has a number of features, such as magneto ignition, not to be found on the one listing at a lower figure.

**Shoemaker.**—This is a car whose builders, the Shoemaker Automobile Company, Freeport, Ill., showed that they had every possible confidence in the merit of their construction by entering one of the first cars they ever built in the grueling 1,500-mile mud-plugging run of the three A tour last summer. Though its driver and designer traveled in the worst kind of hard luck throughout, he pluckily stuck at it, getting through in excellent shape, and a little study of the construction of the car as revealed at the show clearly tells the story of its enduring qualities. Two models are listed, the smaller or Model B being a 28-horsepower four-cylinder touring car, seating five passengers and listing at \$2,000. Some of its distinctive features are high-tension ignition with storage batteries, disk clutch, sliding change-speed gear of the selective type, final drive by shaft and a 102-inch wheelbase, giving it a weight of 2,100 pounds all told. The Model C Shoemaker is a 40-horsepower car, listing at \$2,500 in complete running order, and is intended to meet the requirements of the buyer who desires more speed, as in every other respect the same high grade material and workmanship is a feature of both.

**Staver.**—This new popular priced car forms an excellent example of the striking extent to which the influence of the desire of the high-priced cars has been felt by the builders of these handy vehicles. For instance, it has shackled full elliptic rear springs and half elliptic front. The 18-20-horsepower motor of the two-cylinder, horizontal, opposed type is supported on a three-point suspension and drives through a two-speed planetary change-speed gear to a countershaft, which, in turn, drives the rear wheels through half-inch Whitney roller chains of one-inch pitch. The engine bearings are Parson's white brass, with phosphor bronze in the gear-set, Timken roller bearings in the wheels and standard roller bearings on the countershaft. The engine is water-cooled by a gear-driven pump and honeycomb radiator, the fan being shaft driven. With a Stanhope body on a 78-inch wheelbase, the car lists at \$1,000, complete with top, curtains, storm apron, gas and oil headlights. The Staver is made by the Staver Carriage Company, Seventy-sixth and Wallace streets, Chicago.

## NEW THINGS IN THE WIDE FIELD OF ACCESSORIES

INVENTIVE imagination has always appeared to run riot in the Middle West, for each succeeding show at the Coliseum and its numerous annexes brings forth an array of ingenious accessories that is little short of marvelous. Of course, it must be added that the Chicago accessories of this year are not always those of the year before or of its predecessor, such as it is customary to see in the slightly more settled Eastern shows. Many of those highly ingenious devices seem to go the way of the majority of revolutionary appliances, whose functions are such that if they worked according to the inventor's claims, the automobilist would have nothing whatever left to do. This, however, is but one aspect of the multitudinous array of small ware exhibits that the visitor finds stowed away in every possible nook and corner of the two big buildings devoted to the pleasure car end of the show. In their ranks are to be found all the old-line makers of standard accessories, such as tires, tops, ignition apparatus, tools, lubricants and lubri-

cating appliances, parts, clothing, and all the thousand and one things that are required by the autoist. The following are some of those whose show activities are confined to the Chicago end:

**Duplex Coil Company.**—For the past two or three years this concern, whose plant is located at Fond Du Lac, Wis., have been marketing a special type of induction coil for high-tension ignition. The chief feature of these coils, as their name indicates, lies in the use of a double core by means of which short primary and secondary windings are permissible. The magnetic force is correspondingly increased, allowing the use of a strong spring and light armature, which make adjustment easy, as well as eliminating much of the trouble ordinarily arising from this source. The duplex coils are built in the best possible manner throughout, and their record on the road during the time they have been on the market is a self-recommendation.

**Echo Horns.**—The Echo horn is a newcomer to the field

of signaling devices that is being shown for the first time in connection with the exhibit of the Excelsior Supply Company in the Armory. It is made by the Echo Horn Company, Teubusch Building, Cleveland, O., and its construction is such as to do away with the disadvantages hitherto inherent in exhaust-blown horns. It is of the three-tube type, no solder being employed and every joint being made mechanically rigid. The sounding device consists of a bronze casting, instantaneously attachable to the body of the horn, which is a second casting into the horns are tapped and screwed up tight.

**Excelsior Supply Company.**—There are so many things handled by such a concern as this that it is practically impossible to attempt to enumerate the many specialties they show, a large proportion of which are handled on exclusive representation in territory. A particularly novel specialty is the Mandeville steering wheel muff, made by a concern of the same name, located in Bluffton, Ind. Another is the "inner shoe," made by the Inner Shoe Tire Company, Grand Rapids, Mich., of specially stretched fabric. They also make "inner shoe patches" and "pinch-proof tube bands." In the

experimenting on the part of the manufacturers, so that they are confident that the Heitger carbureter will do all that they claim for it and a little more. It is light, compact, and very accessible in every part, while its construction is such that small moving parts or fittings have been reduced to the minimum point. One of its great advantages is the sensitive control it permits on the throttle, and the makers are so certain that in this, as well as in other respects, it will demonstrate superiority, that they invite manufacturers of cars and other responsible parties to try it out on their own machines, carbureters being submitted gratis for the purpose.

**Long Distance Radiators.**—According to the claim of the Long Manufacturing Company, 1430-34 Michigan avenue, Chicago, there are now upwards of 22,000 of the long spiral tubing radiators in service—a fact that speaks for itself where the efficiency and durability of the type of radiator turned out by this company is concerned. Their experience in the business of radiator manufacturing dates back several years, one of their patents having been granted as early as September, 1901, while a number of others are pending. Radiators of every standard type are made, while the com-

IN THE LONG GALLERIES OF THE COLISEUM THE MULTITUDE OF ACCESSORIES MAKERS SHOWED THEIR PRODUCTS.

ignition line they are handling the Fry special adjustable spark plug, made by the T. C. & W. L. Fry Company, New York. Webster gasoline gauges are also handled.

**Franco-American Auto & Supply Company.**—One of the first things to take the attention of the visitor at the booth of these purveyors of all things automobile is a new compressed acetylene gas tank, which has just been brought out by the Commercial Acetylene Company, Indianapolis, Ind. It is termed the "Stereo" tank, and is the result of an effort on the part of the makers to bring a convenience of this kind down to a price point where it will be available to the owner of the small car who could otherwise not enjoy it. It is really a miniature edition of the larger tanks in most respects and has a capacity sufficient to supply the smaller headlights used on light cars for about the same length of time as its larger prototype does on the big cars with their more powerful headlights. Some of the other specialties handled by this firm are the Helmet oils, Index speedometers, Look sparking batteries, Long & Mann tire tools, Champion auto tool kits, Cincinnati portable electric drills, Amco tire holders, and numerous others.

**Heitger Carbureter.**—Though the new type of carbureter being marketed by the Heitger Carbureter Company, Indianapolis, Ind., was brought out some time ago, this is its initial bow at a show. It embodies numerous distinctive features that are the result of long study and continued

company is also in a position to figure on special requirements of any nature in this field. In addition, they also specialize on a most complete line of hoods, dashes and fenders of all types. Owing to their situation, they are in an excellent position to handle repair work, and accordingly maintain an excellently equipped department for this purpose.

**Mandeville Steering Wheel Muff.**—No one who has not had experience in driving a car in winter can fully realize what the conditions are, so that it took a driver to evolve a device that would keep the hands properly protected and still permit of freedom in handling the wheel. The inventor was W. Harry Mandeville, and his device is called the Mandeville Steering Wheel Muff, which, as its name indicates, is designed to keep the entire wheel covered, thus making it unnecessary for the driver to put his hands on the cold wood every time he turns a corner. Moreover, the muff affords a most effective protection for the wrists and forearms by keeping out the wind and drifting snow, and, what is equally important, it also prevents the latter from getting on the throttle and spark control levers and into the steering column. The muff is made of good quality leather with fur lining, and for those drivers who wish to see the position of the control levers is made with a celluloid window. While the greatest thing of the kind brought out for pleasure car drivers, it is indispensable to the truck driver, whose exposed position and slow speed

G & J TIRES WERE SHOWN IN A GOOD CORNER LOCATION.

keep him in the cold for long stretches at a time. The muffs are being manufactured by the Mandeville Steering Wheel Muff Company, Bluffton, Ind., and are also made in summer styles for bad weather.

**Never-Miss Spark Plugs.**—This is a plug of special construction, made with both porcelain and mica insulation, by the Never-Miss Spark Plug Company, Lansing, Mich. The name is suggestive of satisfactory ignition service on the road, at least where this essential is concerned, the makers stating that the peculiar and original construction of the Never-Miss plug does away with common plug troubles.

**Pfanstiehl Laboratory.**—The exhibit of this concern is one of the most attractive of the number of makers producing ignition apparatus, as in addition to their usual lines of "caterpillar flame" automobile coils their showing includes a tremendous x-ray coil in working order, and, as an estimate of this nature calls for the highest skill of the electrical apparatus manufacturer to turn out successfully, it will be evident that the presence of this monstrous coil at the booth of the Pfanstiehl Electrical Laboratory of North Chicago, Ill., has a definite bearing on the remainder of the exhibit, and is not there merely to attract the attention of the curious. In brief, it means that every Pfanstiehl unit is an x-ray coil.

**Ross Steering Gears.**—The tubular type of steering gear manufactured under their patents by the Ross Gear & Tool Company, Lafayette, Ind., is of a special design, embodying many exclusive features. This is known as the Model B A and has been designed particularly to meet the demands of heavy truck and large touring car service, in which an absolute back lock is essential. The Model B B, which is of the spiral type, has the same advantages as the first named, but gives a fore and aft motion of the arm. In this design the back lock is obtained by giving the spirals on the housing a long lead. Other models of steering gears made by this firm are a lighter type of the tubular pattern, and a new form of disk steering gear known as Model B D, which constitute a radical departure from current standards.

**Schilbach & Beecher Wind Shields.**—It is hardly necessary to call attention to these shields as a thing particularly new because the former has been on the market for some time—long enough, in fact, to have upwards of a thousand of them in daily service. Its construction is such as to entirely do away with hinges, while another unusual advantage is the fact that the appearance of the shield is the same whether the top is up or down. It is furnished in full brass or solid mahogany with brass trimmings, and is made to fit any standard type of car on the market. The Beecher is also a most practical and easily worked shield, particularly for a low-priced article. The adjustment is by means of a small wheel on either side, which firmly holds the shield at

any angle. The Voltz is another ingenious and simple shield made by this concern, the Limousine Carriage Mfg. Co., Michigan avenue and Thirty-fifth street, Chicago.

**Visor Hood and Muffler.**—It is not often that a single article of apparel can be put to the manifold uses of which the new Visor Driving Hood and Muffler is capable. It is made of hand-knitted pure wool throughout and can be used as a neck-muffler and chest-protector, as a driving hood, face protector, or as a sleeping cap, any of the changes being readily effected in a few minutes without the aid of another person, and without using any outside attachments, two fasteners keeping it in place regardless of the manner in which it is employed. It is made by the Visor Knitting Company, Niagara Falls, N. Y., and Toronto, Ont.

**Vivax Storage Batteries.**—These light accumulators are the result of several year's experimenting, with a view to the production of a battery specially designed both for ignition and electric vehicle use, in which the requirements are unusually severe, although the makers, the Vivax Storage Battery Company, 2224-2234 Michigan avenue, Chicago, also produce large cells for central station use. For ignition work they are made in sizes suitable for two, four, or six-cylinder cars, and with a properly adjusted coil not taking more than .75 ampere, will give a mileage of 1,200 to 1,500 on a single charge, while for limousine lighting they will burn three four-candle power, six-volt lamps.

**Warner Clutch Company.**—It took the automobile designer quite some time to realize that the character of the clutch employed on a car had a very vital influence on the life of the gear-set, and this is one of the things that the makers of the Warner clutch, the Warner Clutch Company, 1461 Michigan avenue, Chicago, have borne in mind in perfecting their device. Elimination of shocks in starting is absolutely essential to this end, and the fault with early devices was that the necessary slippage could not be obtained without damaging the clutch itself. It is also of the greatest importance that the clutch should release instantly, and both in this and the matter of slippage the Warner clutch has been brought to a high state of efficiency.

DIAMOND TIRES AND TIMKEN BEARINGS WERE NEIGHBORS.

LOCOMOBILE LEAVING ON ITS LONG PLUG THROUGH WESTERN MUD.

a prominent part in the scoring. After three days' conscientious work on the road, with a record which would under ordinary conditions have earned a perfect score certificate, it was disappointing to the contestants to find that they had to descend from their proud position because of some such trifling matter as loose or broken lamp, speedometer or horn. All recognize the value of the technical examination at the end of the run, for under the old régime too many ruined cars have struggled practical wrecks to the finishing line and earned equal honors with the strong and sturdy. It is just here that discrimination was needed, stereotyped rules being altogether incapable of meeting every contingency. The public wants to know just these facts revealed by the committee's examination, but drivers were certainly en-

CHICAGO, Dec. 1.—Ten sturdy automobiles actually met all reasonable conditions in the strenuous three-day, 600-mile reliability test of the wideawake Chicago Motor Club, but its technical committee finally succeeded, by a process of elimination, in reducing the survivors to the trio who were awarded the Miles, Goodrich, and New Southern Hotel trophies.

A Haynes runabout, driven by Frank Nutt, escaped without a flaw, thus securing the Miles trophy; the Pierce six-cylinder, tooled by Arthur Kumpf, with but two points to its discredit, gained the Goodrich silver set, a loose grease cup on the rear axle being its undoing, and an Oldsmobile, driven by Ralph Owen, was charged with six points for having "a driving shaft boot loose" and an "emergency brake, medium," but gained the hotel cup.

The test was really a two-part one, and the practice of appointing competing observers made the supervision on the road no less thorough than that applied to the cars by the hard-working committee when they undertook the task of examining them to ascertain the condition the three arduous journeys had left them in. The cars were placed according to price in three different classes: A, B, and C, and were called upon to make an average of 20, 17, and 14 miles an hour, respectively.

Every time the driver had to halt or leave his seat the hawk-eyed observer was his shadow, so that by the end of the three days' work on the road more than two-thirds of the competitors had piled up so many demerits that they had eliminated themselves from all further consideration. First come the ten who survived with flying colors, seven of which later fell outside the prize list beneath the close scrutiny of the technical committee, although it seems unfortunate that accessories should have been allowed to play such

titled to more consideration. Herewith is the list of participants and the official order in which they concluded:

cars to a searching examination and penalizing them for defects according to the schedule adopted. This was as follows:

Front and rear axles.—There will be no penalty when the spread of the wheels is less than 1-2 inch; for each 1-2 inch or fraction in excess, five points.

Springs.—Sag of one inch permitted without penalization. For each additional 1-4 inch or fraction thereof, five points.

Frame.—For each 1-4 inch or fraction thereof, 15 points.

Steering Knuckles.—For each 1-8 inch variation or fraction thereof, 10 points.

Motor Test.—One or more cylinders missing in a two-block test, 50 points.

Brakes.—Failure to stop car within reasonable bounds, 30 points.

Transmission.—Failure to drive on different forward and reverse speeds, 50 points.

Clutch.—Perceptible slipping, 30 points.

It will be recognized that the above rules were most admirably framed to demonstrate the fitness of a car to survive such a test, but, as has almost invariably been the case in the past, so many cars have demonstrated such fitness in no uncertain degree that the committee found themselves extremely hard put to it to devise some way of eliminating. Consequently, although it was understood at the outset that the rules applied both to the car's equipment as well as to its mechanism, the construction put upon them was such as it would be found difficult to read into the regulations, though it must be added that in their application the committee was consistent throughout. For instance, Sheridan's White steamer was penalized six points for having a side lamp perceptibly loose, and right here is where the committee might have exercised its own judgment in the matter rather than trust to the competing drivers. Upon the discovery of such a defect the driver was called and asked how long it would take to make good the repair, the penalty being based on his answer, and as the answers varied as widely as the poles, so did the penalties for equally trivial adjustments.

For instance, Arthur Kumpf, the juvenile driver of the Pierce

How the Test Was Conducted.

The three days' test was split into three sections: going to South Bend, Ind., and back the first day, a distance of 221 miles; to Rockford, Ill., and back, 190 miles, the second day, and to Ottawa, Ill., and back, 205 miles, the third day. The rules prevented any repairs or replacements without penalties and everything possible on the car was sealed. Observers nominated by the factories were used. The technical committee consisted of David Beecroft, F. E. Edwards and Berne Nadal, assisted by Frank H. Trego. Referee was F. C. Donald, president Chicago M. C.

Placing competing observers on all the cars resulted in lynx-eyed supervision during every moment of the running, while the cars were locked up between each day's run and after the final. Friday afternoon the technical committee, which had worked continuously for three days and nights, undertook the task of ascertaining the condition of the claimants with pretensions to perfect scores. This consisted of subjecting the

OWEN MADE THE OLDSMOBILE A CLOSE THIRD.

THE LITTLE AUBURN WAS ALWAYS RELIABLE AND STEADY.

Great Arrow Six said it would take half a minute to turn down a grease cup on the differential housing, but which did not need turning down anyway. This placed a black mark against his otherwise clean score, and it must be added that the big Pierce had gone over the course twice, so that its test was nearer 1,300 miles than 600. "Ted" Collier's Rambler was assessed one minute or two points for losing the red lens out of the tail-lamp. Leitch's White steamer, No. 23, was assessed no less than six points merely on account of a cut apron lacing which had suffered from a gravel pile on the road. John Haynes' Dragon had a loose engine pan and Ralph Owen's Oldsmobile suffered 2 1-2 minutes for a small set screw loose in the universal joint housing. These last, it will be noted, were purely mechanical troubles and well within the scope of the regulations, as were also those more serious ones, such as the bent front axle on the Stevens-Duryea "Big Six," which occurred early in the trials, and which it was evident to all would penalize the car in spite of its perfect running record, much of which was made under this serious handicap; and navigating Illinois roads at speed is not child's play, even with a perfect car.

Instances of the first sort multiplied themselves indefinitely, so that practically the entire afternoon was spent in the examination of the cars, and but few of them were given their round-the-block test to be weighed in before darkness settled down, while the committee wrestled with the problem of coming to a satisfactory basis of judging at their headquarters in the New Southern until a late hour Friday night. Next morning they went at the task again and last night the decisions were made known at the show.

#### Story of the First Day's Run.

As a curtain raiser the worst route between Chicago and South Bend was selected, and as the distance was 230 miles for the day's running, it was evident that the committee was determined to begin the weeding out process as early in the game as possible. Many of the competitors helped this plan along by starting out with such a slam, bang dash style of running that they eliminated themselves. C. A. Coey, driving the Thomas Flyer, settled his chances before he got beyond the Chicago city line, going into the ditch at One Hundred and Twenty-seventh street and Michigan avenue, while traveling at high speed. His observer, R. I. Eads, of the Premier company, was scratched up a bit, and C. E. Gregory, treasurer of the Chicago Automobile Club, who was a passenger, catapulted through the air, but landed safely. Before traveling 25 miles, R. W. Cook's Royal Tourist broke its rear axle, but Cook never said die and jumped on the first train, bringing back a new axle with him, causing a loss of 4 hours 45 minutes, half of which was made

SUCCESSFUL PIERCE, WITH ITS YOUTHFUL DRIVER AND BIG HAPPY FAMILY.

up before the end of the day. C. W. Price's Marion had axle trouble also, while the Frayer-Miller, driven by J. Barnes, cracked its frame, thus making a total of four cars wholly eliminated on the first day.

Those who participated in last summer's A. A. A. tour have reason to remember the roads between South Bend and Chicago, and they will not wonder that the end of the first day's run saw no less than 12 of the 35 cars with black marks against them. Some of these were from trivial causes, such as the 16 points chalked up against the Matheson, whose driver had to resort to a piece of string to prevent the sprag from dragging, though losing some 235 points owing to trouble with a radius rod. A trifling brake adjustment cost the Locomobile 10 points. No. 13 was an ill-omen for the Maxwell, as it lost 334 points through motor troubles, though it made all controls on time. The No. 2 Pierce four-cylinder car lost 51 points.

#### How They Ran the Second Day.

The second installment was to Rockford and return, a distance of 189 miles. Taken all in all, the roads were an improvement over those of the first day, and there were stretches where even the most conservative would have found it hard to resist the temptation to "let her out." The Autocar, driven by Barney Oldfield, suffered to the extent of 56 points; the Premier gath-

ALL THREE MEMBERS OF THE WHITE FAMILY FINISHED IN GOOD CONDITION.

ALL THE LIGHT-WEIGHT PASSENGERS WERE NOT WITH JACKSON.

ered 35 points; the National got 4; the Studebaker the same number; the Rapid 'bus, the performance of which was one of the marvels of the run, added 29 to its initial gathering of 75 on the first day, but it brought its load of twelve passengers into every control, and the way it burned up the road with its load of rosters was the delight of the many farmers who lined the roads.

The four points placed against the Studebaker resulted from the driver's placing a chip of wood on the exhaust to hold the muffler cut-out open, which he did on the assurance of the observer that this did not constitute the use of tools and was accordingly permissible. E. Q. Cordner, the local Studebaker representative, filed a protest against the committee's penalization.

#### Penalizations on the Last Running Day.

It was generally considered that many of those who had survived the grueling of the first two days' runs with credit would fall under the ban through minor causes on the last tryout, though the number which succumbed was not nearly as large as many had anticipated. The No. 2 Pierce-Arrow four-cylinder car, driven by Paul Hoffman, got through without adding to its initial 51 points lost on the first day, but the No. 6 Matheson fared badly, as it was necessary to break the bonnet seals at the early morning getaway in order to start the motor by pouring warm water on the carbureter, thus utterly ruining an otherwise perfect record, which would doubtless have been maintained to the end. It was assessed 401 points. The Wayne roadster was another to hopelessly damage its otherwise perfect record by colliding with the Maxwell, thus breaking its right steering knuckle and incurring a penalty. The Jackson touring car was penalized 50 points; the Autocar roadster gathered 2 points more, while the Maxwell, which traveled in hard luck all the way through, but pluckily stuck out the 600 miles,

IT WAS COLD TRAVELING ON THE SPEEDY STODDARD-DAYTON.

JOHN HAYNES HANDLED THE LITTLE DRAGON RUNABOUT.

raked in no less than 610 points. The Rapid 'bus could not escape an additional 66 demerits, but if its total loss of points for the three days had been five times as great it could not possibly detract from the excellent performance of this machine. The No. 26 Matheson roadster and the No. 27 Stoddard-Dayton six-cylinder car did not start on the last day, while the No. 25 Reo runabout, which had only 38 points, gathered on the second day, against it, was put down in the committee's black book for having improvised a third seat by nailing a chair seat and back on the footboard in order to provide for a third passenger.

#### DETAILS OF THE PENALIZATIONS.

While many of the penalizations in the final summing up seem to be carrying things to an absurd extreme in the effort to eliminate possible winners, it must be added to the committee's credit that it carried a most thankless job through in a most conscientious manner. Herewith is the final official score of the event:

- No. 14. Haynes—Perfect score. Official weight, 2,690 pounds.
- No. 29. Pierce—Points lost: grease cup loose, 2 points. Official weight, 4,020 pounds.
- No. 30. Oldsmobile—Points lost: emergency brake, medium, 2 points; driving shaft boot loose, 4 points; total, 6 points. Official weight, 2,790 pounds.
- No. 3. Rambler—Points lost: pedal brake, medium, 2 points; lamp damaged, 4 points; speedometer loose, 2 points; total, 8 points. Official weight, 2,875 pounds.
- No. 18. Auburn—Points lost: wheels and spindles out, 10 points.
- No. 23. White—Points lost: running board loose, 6 points; apron loose, 6 points; total, 12 points. Official weight, 3,510 pounds.
- No. 33. Locomobile—Points lost: fan belt off, 2 points; emergency brake, medium, 2 points; grease cup loose, 6 points; fender loose, 2 points; speedometer loose, 2 points; total, 14 points. Official weight, 3,710 pounds.

SEEING ILLINOIS ON A "RAPID" WAS AN EXPERIENCE.

## NOTED IN THE MERGING OF THE TWO SHOWS

BY CHAS. E. DURYE, OF THE AMERICAN MOTOR CAR MANUFACTURERS' ASSOCIATION.

CHICAGO, Dec. 3.—Chicago is a city of ample elbow room, and Chicago's elbows are busily employed, with the result that even an auto show covers lots of space and presents a wide variety. Here both the licensed makers and the independents, together with a goodly number of outsiders, show in harmony, making it the most representative single show of the year, and of such mammoth proportions that three buildings are filled to overflowing. Magnificent decorations and the separation of the commercial vehicles from the pleasure cars, both add to the harmony, beauty, and practicability of the exhibition.

Chicago, the scene of the first automobile event in America, twelve years ago, has ever been to the front in this line, and the Chicago shows have been interesting because of the variety of vehicles exhibited. This year is no exception, and the motor buggy, shown at Chicago for several years, is rapidly becoming an accepted factor, and Holsman, formerly laughed at by the makers of more conventional products, is now admitted to have shown good judgment and has quite a numerous following.

The two-cycle motor, also a product of the West, having been shown by Mitchell and Pierce several years ago, is now exhibited at this show by a maker from the extreme East, on the Atlas cars, as well as by others.

The friction-drive, another Western product, first shown at Chicago, is now largely in evidence on a goodly number of vehicles, particularly on a large proportion of the commercial vehicles; being shown on the Lambert cars, both for pleasure and business, where it has for years past proven its value, because of which fact it can no longer be regarded as an experiment, and purchasers need have no fear as to its practicability when properly made.

### Standardization Still of the Future.

We often hear remarks to the effect that the automobile business is becoming standardized, but a study of the exhibits at Chicago shows very clearly that this is not the case; that, on the other hand, the exhibits diversify much more than they did two or three years ago, when the five-passenger touring car was the accepted standard. So long as individual tastes vary we will find an increasing diversity in motor vehicles permitted by the various possibilities in engine kinds and sizes, as well as by the widely varying seating capacities required by different purchasers, and the Chicago show exhibits this wide variety much more fully than did the Palace show at New York. There will always be some people wanting single-cylinder motors, like the Reo and Cadillac, although others prefer four-cylinder vehicles at practically the same price, like the Ford, while still others prefer six and even eight cylinders, not to mention steamers and electrics.

Another potent reason for diversity is the differing needs of the purchaser, who for city and social use buys the enclosed limousine of moderate power and of luxurious finish and appointment. But for touring, purchases the conventional touring car, low hung, with long base and ample power and particularly chooses for flexibility and easy riding, machine specially built with this end in view. While for city use and ordinary everyday service he buys a little runabout or one of the medium powered touring cars, or if he is a busy doctor, possibly a motor buggy.

### Road Clearance Receives Consideration.

Other things also influence his decision, such as the roads over which the vehicle is to be used, so that where a few years ago 28 and 30-inch wheels were the rule, to-day there are examples of 38-inch, as in the Gaeth, and 36-inch wheels are quite common, particularly on the high-speed machines. Road clearance is now given more consideration; the low clearance of the average foreign machine having been found unsuitable for American roads, and therefore having given way to a more compact de-

sign which raises the mechanism without raising the body, with the result that, although having more clearance, the bodies are lower hung and the passengers are carried in a safer and more comfortable position than in former years.

In the mechanism itself greater diversity exists than in former years, and almost every detail may be seen at this show in many modifications. Transmission gears are found combined with the engine near the front of the vehicles, in a separate case at a midway position or combined with the balance gear on the rear axle, while vague promises of cars without transmissions occasionally are heard. The once almost universal cone clutch has been largely replaced by the multiple disk, but expanding and contracting bands are seen in many instances, and the use of the band for braking purposes would indicate that it is amply able to serve as a clutch, and that we may expect a much greater number of band clutches than we have had in the past.

### Position of Throttle and Spark Lever.

Even in features directly connected with the control of the car, such as the position of the throttle and spark levers or the arrangement of the foot pedals, there is a considerable diversity; the spark control being sometimes under the foot and at other times inside or outside of the wheel, sometimes on the left, again on the right, and in still other vehicles at the bottom or at the top. In a few instances the controlling lever is not stationary on the wheel column, but moves with the wheel, from which it will be seen that even in so simple a feature as the position of the throttle or spark lever there are nearly a dozen different arrangements. Yet it would seem reasonable that in the controlling equipment a standard practice should be followed, so that users might find themselves at home on any type of car, instead of having to accustom themselves to each controlling group.

The reason this is not done lies in the different needs of the purchasers, as seen by the makers who prefer to arrange their vehicles in the simplest and handiest manner which they believe will be most satisfactory and least tiresome to their users, rather than adopt the arrangement employed on some other vehicle which they consider less satisfactory.

### Diversity Extends to Minor Parts.

This diversity extends also to the minor parts, such as the cooling fans. Here it would seem reasonable that the ordinary four-bladed fan developed by years of use as the most efficient device for throwing air in connection with the small economical motors, found in nearly every office in hot weather, would be employed almost generally; but such is not the case. Instead there is a wide range in the number of fan blades, reaching a dozen in number in one or two instances and varying also in shape, from a straight, narrow spoke-like blade to ovoid and fancy designs. Some of these fans are housed to direct the air in its intended path; others are in the open, and depend upon the shape of the blade to accomplish this purpose.

It would seem that in details of this kind, where the purchaser is interested only in results, that it could be determined by experiment which fan is most efficient for a given size and power, and that this most efficient form should become universally used.

For years users have hoped that tires would become standardized, but with greater diversity in wheel sizes and the adoption of quick detachable rims by many makers without the abandonment of the older forms, there seems to be no promise that this result will come about.

It is quite evident from this show that in the near future a separation must take place and different classes of vehicles will be exhibited in separate buildings, possibly at separate times, and that diversification is bound to increase.

ON THE OPEN ROAD WITH THE GEARLESS GREYHOUND SIX-CYLINDER AS A THROTTLED COMPLACENT REARGUARD.

## HOW A SIX-CYLINDER AUTO HELPED A VETERAN WALKER

CHICAGO, Nov. 30.—Seven hundred and thirty-five miles on the low gear at the rate of three to four miles an hour, over roads that defy description, is a feat no less marvelous for an automobile than that of the 1,200-mile walk of Weston, the pedestrian, whose performance was the occasion for it. John W. Breyfogle, vice-president of the Gearless Transmission Company, Rochester, N. Y., and George D. Wilcox, its manager, in a spirit of athletic good-fellowship, decided that helping the veteran pedestrian on his trip to Chicago would constitute a test for a car such as had never before been undertaken. There are records and records of every imaginable nature, but the palm for making a slow pace, hour after hour, often for twenty hours out of the twenty-four, without heating or trouble of any nature, must certainly be handed to the Gearless Greyhound, and some idea of what the performance of this 75-horsepower six-cylinder car means may be gained from the fact that few, if any, of the drivers of low-powered cars who turned out by the score to join the procession at different towns along the way found it possible to maintain the slow pace for more than a few miles at a time. Not an involuntary stop was made, the only replacement being a burst tire, which was run flat till Weston halted.

Equipped with two 12-inch Rushmore searchlights—the largest automobile headlights to be had—and a unique buffet kitchen improvised over the exhaust manifold of the motor, Manager Wilcox and Mr. Breyfogle joined Weston at Rochester, November 12, leaving there shortly after noon. Both were familiar with the route and road conditions along the way through having driven over it previously. The pair took turns at the wheel, and as Weston did far more walking than sleeping, one of them found it convenient to bunk out on the fender of the car.

When seen at the Illinois Athletic Club, Weston simply bubbled

over with enthusiasm regarding the aid which the automobile had rendered him. "Made it possible to cut off at least ten hours from the record," he said, "and saved fully half the fatigue of stumbling into the ruts and mudholes, the lamps making it as light as day. But the old man, in his ignorance of things automobile, made it doubly hard for the sleepy driver of the car at night, as he would drop back without warning from his place, ten or fifteen feet in advance of the car, to warm his hands on the radiator, or to place on the car one of the endless gifts that enthusiastic admirers along the way handed out. Even at that slow speed, to have struck him would doubtless have ended the walk, so that the strain on the driver may be imagined. And how long-drawn-out a process this was may be gleaned from the fact that toward the last Weston walked almost continuously, one of his stretches being from Sunday morning at 12:08 (midnight) to Tuesday afternoon at 4:10, during which time he only stopped fifty minutes all told, covering ninety-five miles.

But neither the light nor the protection the automobile afforded was superior to the service it rendered as traveling kitchen of the "Johnny-on-the-spot" kind. Weston carried a whistle constantly and a blast on it was the signal for the driver-chef to get busy. The man off duty would put the cans of coffee, milk, or soup on the "gas stove," or even get ready to "boil two medium"; the driver would speed up a bit and the kitchen would be in full blast.

To protect Weston from the crowds which fairly mobbed him, Wilcox attached two 50-foot pieces of stout rope to the forward dumb irons, and when a town was entered the ends of these would be handed out to the most prominent of the local authorities that could be corralled. With the aid of this improvised cordon Weston could proceed undisturbed.

LAST CALL FOR SUPPER ON THE "DINING CAR."

MAYOR BUSSE ESCORTING THE HERO AT THE FINISH.

# LEARNED IN THE PROCESS OF EVOLUTION\*

BY CHARLES B. HAYWARD.

DOCTORS' mistakes are said to be put under six feet of ground; lawyers' errors often hang, while those of the cloth are said to arrive at the wrong destination. But who pays for the automobile designers' slips? The buyer of the car naturally has to foot the bills every time, or, as it is expressively put in the vernacular, "the dear public pays the freight." It may seem unfortunate that, over and above the first cost of a car, its purchaser should have to pay for fundamental errors of design or poor judgment in the choice of materials, but experience in whatever line has to be bought dearly, and had it not been for the lessons learned from a great number of cars it is quite probable that the development of the automobile would not have advanced at the extremely rapid rate that it has. A rope that is almost severed will frequently stand an amazing load, and a poorly built car of cheap materials will often give satisfactory service, as is borne out by the sententious observation of the New

FIG. 1.—Typical instance of defective design, insufficient material in the cheek

York agent of what was probably as cheaply put together a machine as has ever been marketed in quantities. "Some of our customers never have any trouble, but a great many of them can't go ten miles without having something break." A statement illustrative of the chance destiny that causes some to succeed while others fail, though all be cast in the same mold.

### Some Parts that Break Oftenest.

It also seems particularly unfortunate, at least from the viewpoint of the owner of the car, and who is in consequence paying for the designer's experience, that expensive parts should have such a habit of giving way. For instance, crankshafts are among the commonest and at the same time the most costly parts of the

FIG. 2.—Somewhat of a freak design, this crankshaft being designed for a motor no larger than that of Fig. 1.

\* Photographs by the author.

car to replace. In the course of little more than one month 26 instances of broken crankshafts were reported on one of the best-known foreign cars that is imported into this country. That is, this number were brought to the local agency for repairs, some of them being illustrated by photographs in connection with this article, but of them more later. Right here a momentary digression may be made to remark that it is not the cheap car that is always giving way by any means. Of all the cars with which the present deals, whether directly or indirectly, more than 90 per cent. of the broken parts were from some of the highest-priced cars made on either side of the Atlantic—cars in which it is to be presumed, judging from their selling price, if nothing else, that no pains or expense had been spared to make their design

and construction as advanced, an example of the automobile builders' art as it was possible to produce.

Front axles, frames and springs are other equally expensive parts that have a habit of giving way when least expected, and of these three probably the last-named is the most common. As a matter of fact, the frequency with which springs give way shows conclusively that there is a great deal of room for better-

FIG. 3.—This is a repetition of the same fault as that characterizing Fig. 1, and occurred on the same make of car.

ment in this essential, and this is one of the things in which choice of poor material is most often found to be at the root of the trouble, though incorrect design plays its part here as elsewhere. For instance, it avails little to supply the best spring that money and skill can create, if it is to be held on its saddle by U bolts of common wrought iron or Bessemer steel from the hardware dealers' stock. Under such conditions the spring does not remain rigidly attached to the axle for any great length of time, as the strain soon causes a permanent set in the bolts, frequently amounting to 1-16 inch or more, permitting the spring to crawl. Then, instead of absorbing the shock through its leaves, as would be the case were it rigidly clamped down, the whole spring is lifted and thrown bodily against its support, before this dampening action can begin, and the result is a break. In consequence it is found that the springs usually give way under the clamps. Steel comparatively high in carbon usually

FIG. 4.—Three from a batch of more than a score, all of which broke in the same place in little more than a month.

about 60 point, is the material most commonly employed for this purpose and serves its ends satisfactorily—more so since the requirements have come to be better understood. It has been found that the semi-elliptic spring is exceedingly sensitive and on that account particularly desirable where roads are good, as is the case abroad, but its limited range of action does not fit it for extreme shocks, and the full elliptic type is much more favored on American cars, those designers who retain the former making it very much longer than was formerly thought necessary.

FIG. 5.—Extreme instance of crystalline structure in aluminum alloy

To the experienced eye every broken crankshaft tells its own story, and when this important essential breaks faster than the agent can make replacements, and all the breaks are in the same place, it would not appear as if the significance of the wholesale defecton were very deeply hidden. This is the case already referred to, in which at least 26 owners who had paid for high-priced foreign cars found occasion to go to the expense of replacing the crankshafts in the course of a month. There may have been more, but certainly the number cited was enough to point the moral, and the group of three shown by the accompanying photograph, Fig. 4, speaks for itself. As will be noted from this, all have given way at exactly the same point, two of the ends being shown, while the third is missing. From the designer's point of view this was the "right place" for those crankshafts to break, if there can be said to be such a thing. In other words, it sufficed to show conclusively that not the design but the material was at fault. This is made clear by reference to Figs. 1 and 3, taken from an American car—a high-priced one at that—which are typical examples of defective design, an insufficient amount of metal being allowed in the cheek where it joined the crank pin. But examination also proved the material to be defective, being too high in phosphorus, and consequently what is termed "cold short," tending to brittleness. In this connection it may be mentioned that carbon steel possesses the peculiar property of splitting or running when notched or nicked, and this quality has caused trouble with crankshafts drilled for oil holes.

But to return to the group of broken shafts—these were all taken from one model of the same car—one of the highest-priced machines that is imported into this country. It will be

FIG. 6.—Four expensive breaks, all on cars of the same high-priced make and all due to the same cause—improper material.

noted that the rupture invariably occurred at the point of maximum load, between the flywheel and the fourth crankpin, a point where the summation of all the stresses is centered. The breaks were due to flexure of the material, which was not sufficiently rigid to stand the constant bending strain without giving way—a fault that seriously affects the dynamic life of the part with the result so strikingly depicted by the photograph—and it may be added, so painful to the owner of the car. The crankshaft illustrated by Fig. 2 is merely shown as an instance of what extremes designs may sometimes be carried to. In the first place, this crankshaft has sufficient metal in it to transmit several times the power of the engine for which it was intended. The designer's idea in giving it this shape was to evolve a three-bearing crankshaft which could be easily machined in a lathe, the space ordinarily occupied by giving the intermediate connecting cheeks a staggered relation, being filled by large blocks which were drilled to reduce the weight. But it will be noted, by referring to cut, that in drilling these a far thinner web has been left than is employed in the other cheeks, which would seem to indicate that the others

FIG. 7.—First, an instance of high-priced material of the wrong kind; second, the result of abuse of the best of materials.

were unnecessary, which, in fact, is the most striking characteristic of the whole piece, as it is not intended for use in any larger motor than the other shafts shown on this page, the pictures all being in the same proportion. While, so far as known, it has not occasioned any unusual trouble, it would appear to constitute a good example of how not to make a crankshaft. Before leaving the subject of crankshafts, it may be stated on the authority of a designer who has probably had a better opportunity to find out the weaknesses of a great many cars than often falls to the lots of his confrères that some cheap American engines of several years ago actually had cast iron crankshafts and that he never saw a broken one—a fact that illustrates the point that where the metal has sufficient initial rigidity and is free from internal strains it will serve this purpose as long as its rigidity is not disturbed.

**Frames and Front Axles Frequently Go.**

Doubtless the average observer would ask what the driver of the car happened to collide with to cause the four petty specimens of frame breakage shown by the photograph, Fig. 6, and would be correspondingly surprised to learn that, in the current slang of the day, these frames simply "laid down." They were not in a wreck or collision of any kind. All are from different cars, but of the same make and of high-priced French construction. They gave way simply because they had come to the end of their life—all are flexure breaks. The point of bending of the material was fixed at a point far below that necessary for such requirements, and having withstood the limited number of shocks of which it was capable of resisting it had come to the end of its dynamic life. The usual point of frame breakage is the rear end of the front spring, and it shows the fallacy of reducing the section of the side frame member excessively, though binding of the hanger is sometimes responsible. As a matter of

fact, however, the frame seldom defaults except in cases of extreme stress, such as could not be adequately provided for by any reasonable design—in short, wrecks and collisions.

Front, axles, however, are in quite a different class—in fact, they form a rather close second to crankshafts, one European car that bears an excellent reputation having a record of sixteen failures in this essential during a comparatively short time. It was not merely a case of poor metal, but a poor distribution of the metal at a load-carrying point—between the spring hanger and the steering knuckle, another equally prominent foreign car having suffered similarly in spite of the fact that the material was all that it should have been. The story is really one of wheels within wheels, for the design of the latter was faithfully copied by that of the former before its originator had had any experience in its use, but the copy was a Chinese imitation in that extremely poor material was employed to execute it. As already mentioned, front axle breakage is most common between the spring saddle and the steering knuckle, and in the attempt to save weight excessive reduction of the section of the axle had been made at that point. On later models of the first-mentioned car it was noticeable that the reduction or I-beam section at the point in question was scarcely more than a surface indentation and was presumably for appearance sake only, as the amount of weight thus saved would be practically a negligible quantity.

**Minor Parts that Wear and Break.**

It may occasion the experienced autoist no little surprise to note that as yet nothing has been said of the shortcomings of the gearbox. The truth of the matter is, so much attention has been given to this essential that it has reached a point where, in the words of a well-known designer, "it is above suspicion." From being the most prolific source of expense where mechanical replacements are concerned, it has attained to the other extreme. Proper materials, better designed teeth, accurate cutting and the use of ball or roller bearings sum up the improvements; where it was nothing unusual to ruin a gear-set a season, with legitimate use there is now no reason why the life of this part of the car should not correspond with that of the vehicle as a whole. But that improper handling will do damage, despite the designer's best efforts, is well illustrated by the sliding member

FIG. 8.—Illustrating the fact that no part of the car is immune.

design left anything to be desired—they could hardly be improved upon, and ordinarily the badly worn pinion on the left should have lasted the life of the car. As it is, it forms a striking example of the long service obtainable from proper design and materials under the most adverse conditions. This, in short, is purely a case of poor driver. The man who handled the lever on the car in question was in too much of a hurry to get under way and had a habit of letting the clutch re-engage before the pinions were fully meshed. In this way the entire load was carried by the corners of the gears, and that they were able to do this on slightly less than a third of the tooth surface allowed by the design, as shown by the worn portion, bears witness to the ample factor of safety allowed.

It is doubtless the average layman's opinion that poor material is synonymous with low first cost and that if the maker cared to share his portion of the burden of expense there need be no further ground for complaint on this score. The bevel pinion shown in the upper half of the same illustration, Fig. 7, is evidence of the fact that this is not always the case. It was taken from a

French car that is built in this country under license and is an excellent illustration of misplaced high-priced material. Analysis showed it to be of 13-point Tungsten steel, a nature-hard steel, oil quenched, that was the prize tool stock of several years ago. The pinion in question was replaced with a low carbon steel wheel, and it is safe to say that, barring accident, the new bevel will last as long as anything else on the car will. Steel of this

FIG. 9.—Typical case of extreme bungling in an alleged light racing car.

kind has better dynamic properties and will simply wear out in use, whereas the Tungsten steel is practically non-dynamic and wholly unfitted to withstand shock. Neither the bevel driving unit nor the differential occasion much trouble, owing to the fact that there are so many intermediate steps between them and the source of power that shocks do not reach them directly. This also accounts for the immunity of the cardan shaft, as breakages here are also more or less rare.

**The Maker Paid for This Experience.**

It has already been said that the gear-box is no longer a great source of expense in the way of replacements to the autoist, but this had reference more particularly to the contents rather than to the gear-box itself. Aluminum alloys have always been a source of more or less trouble, but "not when they are properly alloyed and cast" immediately retorts the aluminum founder. There's the rub—not every automobile manufacturer makes his own aluminum castings, and not every maker is fortunate in always getting a supply that conforms to the requirements. One year—it was in the transition period of 1903, by the way—the makers of one of the highest-priced foreign cars found it necessary to call in all the gear boxes that had been sent out on cars of that year's model when the season was well advanced and a large number had been turned out. This was a case in which the error was of so serious a nature that the maker preferred to stand the expense of replacement himself rather than saddle it on the purchaser of the car. A little consideration would seem to indicate that the wholesale breaking of crankshafts chronicled earlier fell within the same category, but unfortunately this was not the case. It seems rather a coincidence that both these costly errors of design should have occurred on the same make of car.

Another instance in which the maker had to foot the bill—in this case unwillingly—is recorded by the illustration of the two broken crankcase arms, Fig. 5. These were taken from a car of French make and of

FIG. 10.—The first of these pieces was not at fault, but the second shows the result of very poor design.

such sterling reputation that numberless American autoists have been quite willing to pay the 45 per cent. duty in order to become the possessor of one. It is not referred to here to its detriment, as it was merely one of those accidents that are apt to happen at times in the best of well-regulated families and on the best built cars, regardless of where they are made. Usually such faults make themselves known before the car leaves the factory, but this was an exception. The New Yorker who purchased it refused to settle for the car and was sued by the maker's representatives. The former enlisted the services of a well-known designer as an expert witness and, divining the cause of the break at a glance, the expert casually picked up a hammer and dealt the offending case a smart blow. The part struck broke into several pieces, which flew about the room, and the result was such a surprise to the intending litigants that the action was never pressed any further. Both the arms shown are from the same crankcase, the one at the right being the part that originally offended, while the other was broken intentionally to examine the nature of the fracture. The crystalline nature of the break in the first is strikingly evident even in the photograph and shows plainly that the metal was burnt. Of eight or ten cases of similar breaks this was by far the worst, but, as already mentioned, was nothing more nor less than an exceptional instance. Aluminum properly alloyed to meet the requirements of this service will pene down under the hammer.

#### Some Unusual Instances of Breakage.

If a designer were asked what, in his opinion, constituted a part of the car least apt to break, he could probably think of nothing that would answer the question better than the starting crank. Yet starting cranks do give way, as evidenced by the substantial specimen pictured in Fig. 8. It only goes to show that some men, when at the end of the crank, are well able to stand the shock of a backfire, and this is not always true of the crank itself. Fig. 9 represents what was originally a differential housing and is an excellent example of what should not be done. It was taken from a specially built racing car and strikingly exemplified the amateur idea of weight saving. The pinions were made microscopical in size, while the cast steel casing would have held down an ocean liner, if properly applied. It is merely a case of a vast surplusage of material coupled with bad design in other respects. The piece shown in the upper half of Fig. 10 represents a differential sprocket housing from a heavy side-chain driven car, but scarcely calls for extended comment, as the result shown was more of an accident than otherwise, both the material and design being good. Beneath it is illustrated an error in design, pure and simple. In this the jaw clutch of the direct drive of a gear-set was made with but two projections, so that when engaging the parts had up to 90 degrees travel before striking with the excessive wear shown as a result.

ANOTHER CASE FOR THE COURT TO ADJUDICATE.

French Gendarme—"Having asked him what he was doing there hidden under the car, he replied that he was hunting a catterpin; consequently we have drawn up a summons for illegally hunting an unknown game during closed season."—*Omnia*.

## THE AUTOMOBILE CALENDAR.

### AMERICAN.

#### Shows and Meetings.

- Nov. 30-Dec. 7.—Chicago, Coliseum and First Regt. Armory, Eighth Annual National Automobile Show, and First Annual Commercial Vehicle Show, National Association of Automobile Manufacturers.
- Dec. 9-14.....—Detroit, Riverview Park Auditorium, Detroit Automobile Dealers' Association. LeRoy Pelletier, manager.
- Dec. 14-21.....—St. Louis, Mo., Jal Alal Building, Second Annual Auto Show, St. Louis Automobile Manufacturers' and Dealers' Association. D. M. Strauss, manager.
- Dec. 28-Jan. 4.—New York City, Madison Square Garden, Importers' Salon. C. R. Mabley, manager.
- Jan. 14-18.....—Hartford, Conn., Foot Guard Hall, Hartford Automobile Dealers' Association.
- Feb. 1-8.....—Providence, State Armory, Automobile Show. Frank M. Prescott, manager.
- Feb. 10-15.....—Detroit, Light Guard Armory, Tri-State Automobile and Sporting Goods Association, Seventh Annual Show.
- Feb. 17-22.....—Cleveland, Central Armory, Annual Show, Cleveland Automobile Dealers' Association. George Collister, manager.
- Mar. 7-14.....—Boston, Mechanics' Building and Horticultural Hall, Boston Automobile Dealers' Association. Chester I. Campbell, manager, 5 Park Square.
- Mar. 9-14.....—Buffalo, Convention Hall, Sixth Annual Automobile Show, Automobile Club of Buffalo. Dal H. Lewis, manager.
- Mar. 21-28.....—Toronto, Canada, St. Lawrence Arena, Automobile Show. R. M. Jaffray, manager.
- Apr. 5-12.....—Montreal, Canada, Arena, Third Annual Automobile and Sportsman's Show. R. M. Jaffray, Mgr.

#### Motor Boat Shows.

- Dec. 7-14.....—New York City, Grand Central Palace, National Association of Engine and Boat Manufacturers. Chester I. Campbell, manager, 5 Park Square, Boston.
- Jan. 1-8.....—Chicago, Coliseum, National Association of Engine and Boat Manufacturers. Chester I. Campbell, manager, 5 Park Square, Boston.
- Jan. 25-Feb. 1.—Boston, Mechanics' Building, National Association of Engine and Boat Manufacturers. Chester I. Campbell, manager, 5 Park Square, Boston.
- Feb. 3-8.....—Buffalo, Convention Hall, First Annual Power Boat and Sportsman's Show, auspices of Buffalo Launch Club. Dal H. Lewis, manager.
- Feb. 20-Mar. 7.—New York City, Madison Square Garden, Fourteenth Annual Motor Boat and Sportsman's Show.

### FOREIGN.

#### Shows.

- Dec. 5-22.....—Berlin, Germany, Automobile Show.
- Dec. 21-Jan. 2.—Brussels, Show, Palace of the Cinquantenaire.
- Jan. 18-Feb. 2, '08.—Turin, Italy, Fifth International Automobile Exhibition, Palace of Fine Arts, Valentino Park. Automobile Club of Turin.
- Mar. 21-28.....—London, Agricultural Hall, Cordingley's Show.
- May 6-20.....—Moscow, Russia, International Automobile Exposition. Automobile Club of Moscow.

#### Races, Hill-Climbs, Etc.

- Dec. 8.....—Paris, Straightaway Aeroplane Speed Test, auspices of "L'Auto."
- Dec. 8.....—Paris, Break-down Competition, auspices of "L'Auto."
- May, 1908.....—Paris, Competition for Agricultural Automobiles, auspices of "L'Auto." (Exact date to be announced.)
- May 10.....—Sicily, Targa Florio, Automobile Club of Italy.
- June 20-July 5.—Grand Prix, Dieppe Circuit, Automobile Club of France. (Exact date to be announced.)
- July 13-17.....—Ostend, Belgium, International Race Week. Automobile Club of Ostend.
- July 20-30.....—Ardennes Circuit Races and Coupe de Liedederke, Automobile Club of Belgium.
- August, 1908...—France, Coupe de la Presse, Automobile Club of France. (Exact date to be announced.)

## LETTERS INTERESTING AND INSTRUCTIVE

### IS FRONT FLYWHEEL PLACING WRONG?

Editor THE AUTOMOBILE:

[991.]—Will you kindly inform me through your "Letters Interesting and Instructive" if there is any mechanical or scientific objection to placing the flywheel of an automobile engine in front, as in marine engines, instead of back of the engine as is done in the majority? I have been told that it is mechanically incorrect and that in engines so constructed there is a greater strain in the shaft when the clutch is let in and that the main bearings are shorter lived. Please go into the matter as thoroughly as possible, as I am anxious to form an opinion one way or the other.

St. Louis, Mo.

ALBERT C. HAUSMAN.

Without going into the matter deeply from a theoretical point of view, it is evident that the location of the weight of the flywheel on the forward end of the crankshaft will impose an extra torsional strain on the crankshaft when the clutch is let in, and this should be particularly noticeable where the engagement is sudden or harsh. With the flywheel at the rear, as ordinarily employed, it will be apparent that the shock of starting is absorbed by the momentum of the wheel before reaching the crankshaft, whereas in the other case it must necessarily be transmitted through the crankshaft before reaching the wheel. However, whether this is really sufficient to make the main bearings appreciably shorter lived, or whether it can be said to constitute a form of practice that is mechanically incorrect, is quite another thing, for the practice of placing the flywheel at the rear end was more the result of accident than otherwise. The cone clutch was then universally employed and it was found most convenient to combine it with the flywheel, though this situation also gives a better distribution of the weight. The Stevens-Duryea, Northern and Maxwell cars are some instances of forward placing of the flywheel that have been consistently adhered to in this country, while in the Motobloc, a French type, the flywheel is centrally located between the two pairs of cylinders. Probably some of our readers who have had personal experience with cars of both types—i. e., in which the flywheel has been at either end of the crankshaft—may throw some more definite light on the subject. Endless mathematical formulæ could be adduced in support of either position, but such evidence does not carry a great deal of weight with the average man.

### WHY ARE VALVE STEMS NOT LUBRICATED?

Editor THE AUTOMOBILE:

[992.]—Will you kindly explain in your columns why it is that automobile manufacturers, without exception so far as my observation has gone, make no provision for the lubrication of valve stems in their motors. It has always seemed to me that it is of as much importance to have the valve stems lubricated as it is of any other part, the valves being a very important part of a motor.

Minneapolis, Minn.

O. A. WEISS.

On the majority of modern motors the camshaft is located in the crankcase and is exposed to the splash of the oil utilized for lubricating the main bearings, pistons and other moving parts. This oil takes care of the lubrication of the camshaft bearings, cams, rollers and the like, as well as the valve push rods, the housings of which are usually open from below for this purpose. The movement of these rods seldom exceeds 3-8 inch, so that, despite their speed, they do not require a great deal in the way of lubrication. Many drivers find that an occasional drop or two of oil allowed to run down the stem is all that is necessary, while others seldom touch these parts of the motor, and we have known cars having overhead valve gear of the rocker arm type to run 600 miles without being oiled. We have known cases of seized valve stems on racers, which could be traced, however, to a breakdown of the lubrication system. The answer to your query would accordingly seem to be that there is no necessity for such provision, but if there are any of our readers whose experience indicates otherwise we should be glad to have their views.

### WHAT POWER AND SPEED WILL THIS HAVE?

Editor THE AUTOMOBILE:

[993.]—I have just completed a four-cylinder motor as follows: cylinders, 6 x 6; exhaust valve, 3 3/8 inches with 3/8-inch opening. Intake valve the same; exhaust valve has 1-4 inch; lift intake has 3-16 inch; lift valves are on opposite sides; compression, 78 pounds; connecting rods are 12 inches long; the motor is very flexible, and rather high speed. I am going to put it in a touring car and will gear it 2.1-4 to 1, using 36-inch wheels. Kindly state horsepower of same, also how fast motor should turn up, and how fast car should travel at its best.

I would also like some information on the following: I want to use a high-tension magneto with one set of plugs, also single coil, and distribute them as per sketch. I want to use the storage battery, single coil, and distribute for starting and after starting switch over to the magneto. The magneto will be a Bosch.

Baltimore, Md.

EDWIN S. ZELL.

Why not give the exhaust valve the same amount of lift as the intake, as it is equally essential to clear the combustion chamber of burnt gases as it is to fill it with the fresh charge. Ac-

[SKETCH OF MR. BELL'S PROPOSED IGNITION SYSTEM.]

ording to the A. L. A. M. horsepower formula, the output of the motor should be 57.6, but its actual brake output at 1,200 r.p.m. would probably be nearer 80 horsepower. You say it runs very fast, presumably light, and if you will ascertain this speed with a counter, taking two-thirds of it will give you the speed of maximum torque, this rule being found to apply to the great majority of motors similarly proportioned. As you have allowed liberal valve openings, doubtless the free speed of your motor will reach as high as 1,800 r.p.m., or a little over, so that its maximum torque would be reached in the neighborhood of 1,200 r.p.m., though it will probably run as high as 1,500 r.p.m. without showing an excessive falling off in power, and that this figure may be taken in calculating the probable speed of the car. The 36-inch wheels cover 9.91 feet per revolution, or for convenience in figuring, 10 feet. As the gear ratio is to be 2.25 to 1, neglecting any loss from slippage or similar causes, the road wheels will make 660 turns per minute, or about 1.25 miles per minute. The gear ratio is low for a motor of this power and by raising it a speed of ninety miles an hour or over would be obtainable—rather high for a "touring" car in either case.

Referring to your sketch of the proposed ignition system, we have altered this as indicated. As one end of the primary winding of the magneto is grounded on its frame, merely fastening it in place on the car gives the primary ground connection. By taking a wire from the other terminal of the primary

to a switch, one point of which is grounded as shown, the magneto may be cut out by short-circuiting its primary winding, this being the usual method. The secondary connections are taken directly from the distributor on the magneto to the plugs, as shown. One side of the battery is grounded and the other led to the single coil; the second terminal of the primary of the coil is led to the low-tension side of the distributor, a switch being interposed as indicated to permit of shutting off this side of the system. One of the secondary terminals of the coil is grounded and the other led to the distributor, the latter, of course, being grounded in the usual way, the connections not being indicated, in order not to complicate the diagram unnecessarily. Starting is so easily accomplished on the magneto and the latter is so reliable that we should hardly think it worth while to go to the trouble of installing the second system on a home-built car.

**HOW DO RADIATORS DIFFER, AND WHY?**

Editor THE AUTOMOBILE:

[1994.]—Will you please inform me, through "Letters Interesting and Instructive," what the difference is between cellular and tubular radiators, and which is superior? J. E. HARRIS. New York.

A cellular radiator is built up of a great number of small parts, in practically the same manner as a honeycomb radiator is made. These parts are small tubes, their length being that of the thickness of the radiator. They come together at both ends, where they are soldered, but are of smaller section for the remainder of their length, thus leaving thin water spaces between. The tubular radiator is composed of large, flat tubes, covered with radiating fins, and through which the water circulates. From the point of view of efficiency alone, the cellular radiator is superior, but owing to its construction, it is delicate and difficult to repair, so that the tubular type is ordinarily preferred in this country.

**WANTS ENTRY LISTS OF FOREIGN RACES.**

Editor THE AUTOMOBILE:

[1995.]—Being an interested reader of "The Automobile," I would like to ask a few questions. Could you give me the complete entries of the following events: Scottish Reliability Trials, Targa Florio, Irish Reliability Trials, and the Bexhill Speed Trials? These being all foreign contests, I could not find them out, and if you could help me I would be much obliged. L. R. W. New York, N. Y.

These events having attracted a large field of entries, it would be impossible to reproduce the full lists here, the matter being only one of personal interest. If you will give a more complete address than "New York," we will be pleased to give you the desired information by mail.

**SOME INTERESTING QUERIES AS TO PRIORITY.**

Editor THE AUTOMOBILE:

[1996.]—As a reader of your interesting journal, I take the liberty to ask the following. Several makers claim that they built the first six-cylinder car. (1) What American company first marketed such a car (2) Where did the three-point support, as applied to automobiles, originate? What American concern first used the above construction? (3) What American maker first turned out cars having the power plant installed as a unit? (4) I am under the impression that the motor 'buses used in New York City are made in England. Please state what company built them. (5) Is the Darracq the only make of taxicab used in New York City? Brooklyn, N. Y. C. N. S.

1.—We believe the Gasmobile Company, a concern that became defunct the latter part of 1902, should be credited with having offered the first six-cylinder car for sale. It was exhibited in the show in Madison Square Garden in January, 1902, and was generally regarded as nothing more or less than one of the many freaks that each succeeding show of that time brought forth. So far as we are aware, this was the original six-cylinder, but these columns are open to all claimants of the honor. Unless such claims do appear, antedating the foregoing conclusively, the old Gasmobile must be awarded the palm in this respect.

2.—We do not know to a certainty and will have to refer the question to our readers. Both the Stevens-Duryea and the Autocar embodied this form of construction in early models.

3.—This also applies to the unit power-plant, and necessarily so, as the idea is to give both the power-plant and the transmission the benefit of the three-point suspension, and to do this most conveniently they must be combined.

4.—The motor 'buses used in New York City are made in France by the house of De Dion, but the output of the latter has been contracted for by an English firm, which markets them and accordingly affixes its name plates to the chassis.

5.—There are a number of different makes of taxicabs running in New York City, but the Darracq (red) and the Delahaye (green) predominate. Some of the others are the Renault, De Dion, Aries and Chenard-Walker, all of French manufacture, but only having one or two representatives of each make, though all ply regularly for hire.

**WHERE THE FOUR IS BETTER THAN THE SIX.**

Editor THE AUTOMOBILE:

[1997.]—In the October 31 issue of "The Automobile" there was an article by a maker of four-cylinder cars, and in the following issue, an article on the same subject by a manufacturer of six-cylinder cars, in which the latter has taken his four-cylinder opponent so severely to task that, in places, he seems to be hard pressed for material upon which to base a sound argument. As both of these articles were written by manufacturers, perhaps a few words from a private owner, unconnected with the trade, would not be entirely out of place.

Let us consider two motors, one of four cylinders and the other of six, both of the same horsepower. The cylinders of the former would have to be of greater size in order to produce the same horsepower at the same speed. Now the fundamental argument in favor of any type of machine, except in extreme cases, is its efficiency, or, in other words, the ratio of the energy expended in doing useful work to the total energy received. Gas and steam engines are "heat" engines; they transform heat into work, and they are also capable of performing the reverse of this process. The units of heat are called British thermal units, and one B.T.U. is the amount of heat that will raise the temperature of one pound of water one degree; to be exact, distilled water, at or near the temperature of 39 degrees Fahr. temperature, then, of a gas or substance, is the measure of the heat units it contains.

In a gas engine, when compression occurs, the temperature of the gas in the cylinder is raised, and in this case the energy of the moving piston is transformed into heat. When ignition takes place the gas is exploded—the temperature rising several hundred degrees almost instantly—that is, heat units have been added to the gas. It is this heat, or rather part of it, that drives the engine. Under the second law of thermodynamics, the efficiency of an engine

like a gas engine may be expressed by the formula  $\frac{T - T_1}{T}$ , in which T

is the temperature of the gas at explosion, and T<sub>1</sub> is the temperature at release or exhaust. It will be clearly seen that the greater the difference of the temperatures at explosion and at exhaust, the greater will be the efficiency, and the greater the number of heat units transformed into useful work—provided it is all expended in driving the piston, and here we come to the important part.

As a matter of fact, only a small portion of this heat expended in the cylinder drives the piston. One authority gives the distribution as follows:

Work indicated in the cylinders.....	17 per cent.
Heat lost to the cylinder walls.....	52 " "
Heat carried away by the exhaust.....	15.5 " "
Heat lost by radiation and conduction.....	15.5 " "
	100.0

The power of a gas engine increases as the square of the diameter of the cylinder, while the cylinder wall area does not increase so rapidly, and therefore the larger the bore of the cylinder, the less the percentage of cylinder wall surface there is, and the more efficient the engine becomes.

Applying the above to the two engines of equal horsepower, one of four cylinders and the other of six, the former will have the higher efficiency, as the greatest waste of a gas engine is the heat carried away by the water-jacket. This is strikingly shown by the following table of results from tests on stationary gas engines of different cylinder sizes but of about the same amount of compression:

Diameter of cylinder.....	9.5 "	14. "
Stroke .....	18.0 "	25. "
Actual efficiency .....	.21	.27
Theoretical efficiency .....	.40	.41
Ratio of efficiencies.....	.53	.67

Again, the six-cylinder engine will have more friction than the four-cylinder of the same horsepower, for there is the friction of six crank pins, etc., instead of four, and the four-cylinder motor adds to its already better efficiency here.

One might say that the same reasoning could be applied to the two-cylinder against the four. However, with four cylinders there are two impulses for each revolution, the same as a one-cylinder steam engine, and this gives so much better balance than the two-cylinder, and is of such importance, that it outweighs the gain in efficiency and the four-cylinder is to be desired. With the six-cylinder this point does not apply as it would if we were considering eight, for eight cylinders would be equivalent to two steam cylinders.

Few people will deny that two cylinders are better than three. Many two-cylinder cars are built to-day—the Darracq Company is building them—but do you find any three-cylinder motors built this year? Judging from the sad experience of the three-cylinder cars, the future of the six ought to be clearly defined.

The six-cylinder advocate tells us that an engine with six cylinders, of the same size, etc., as four, will develop 50 per cent. more power because it is not a matter of "testing" or "opinion," but "it is the working out of mechanical laws." Mechanical laws may work out to a certain result, but the rub comes when you try to get the same result in practice. Do you get it? The four-cylinder advocate states that after trying to do it, and after testing the matter out carefully for a considerable length of time, that he could not get the 50 per cent. more power. From my own experience, in charge of tests on steam and gas engines varying from 10 to 4,000 horsepower, I should not hesitate to believe the four-cylinder spokesman. And if he, a maker of a successful and reliable car, could not obtain the 50 per cent. more power, is it unreasonable to suppose that another maker cannot do so, when he presumably has not tested it out carefully, since he did not state his results?

Quoting from the columns of "The Automobile" of November 7, page 708: "Six cylinders will be in evidence (Paris), but will certainly not be one of the features of the show. Important speed contests this year, which have much less connection with fashion than automobile shows, have failed to develop any remarkable features in the sixes that are not already possessed by the fours. Leading French makers \* \* \* will produce six-cylinder models, generally as a concession to a popular fad, but not because of any firm belief in their superiority."

Perchance this might explain "Why the public should demand inferior cars (sixes) and still be willing to pay more for them than they do for fours." As the breakfast food man says—"Get back to Nature"—the horse and the greyhound have four, so has the elephant, and here we have usefulness, speed and power, but the six-cylinder man will tell you that this last statement is as irrelevant as carbureters, torque and perpetual motion, and perhaps it is.

E. L. HILL.

Worcester, Mass.

**IN DEFENSE OF THE MANY-CYLINDERED MOTOR.**

Editor THE AUTOMOBILE:

[199.]—It is with considerable diffidence that I take up cudgels in defense of the motor of more than four cylinders against the attack of Mr. Stearns, in your issue of October 31, both on account of the well-known reputation of Mr. Stearns and also on account of the appalling amount that has been written on the subject. If it will not be considered as dodging the issue, perhaps the eight-cylinder motor may be included in the controversy, as offering a more radical contrast with the four-cylinder than the "six" does.

Beginning with the question of torque, which seems to be the crux of the matter, the four-cylinder motor is deficient, as twice every revolution the torque drops to zero. In addition to this, it must be remembered that during the latter part of the power stroke the power is small and rapidly decreasing. In fact, with standard gearing and engine, very few four-cylinder cars would be able to climb a steady 6 per cent. grade on the direct drive, without the help of the energy stored in the flywheel. Considering the eight-cylinder motor as the other extreme, the torque is found to be almost constant. Firing every quarter of a revolution, one impulse begins long before the preceding one is expended. As a gasoline engine delivers by far the greater part of its power during the first half of the piston stroke, the flywheel in an engine of this type has very little to do, and may be quite light without making any perceptible difference in the smoothness of operation.

The statement that it is utterly impossible to notice any difference in the smoothness of running between the best four-cylinder and six-cylinder engines running at a speed of over 200 r.p.m., may be passed over as a matter of personal opinion, but it is doubt-

ful if everybody would agree with Mr. Stearns after driving behind a four-cylinder and also a six, or, better still, an eight-cylinder, up a stiff grade with an engine speed of about 200 r.p.m.

The declaration that "a six-cylinder motor geared, say, 2 to 1, delivers 12 impulses to the rear axle for every revolution of the wheels" and the following comparison with a one-cylinder motor is presumably a typographical error, but the deductions if of any value rather incline toward a preference for a one-cylinder motor over all others, as the question of torque and balance are ignored.

The statement that the six-cylinder motor used 50 per cent. more radiating surface, weighs 50 per cent. more than a four-cylinder motor of the same power, and the other accompanying statements, are hardly borne out by the facts. Indeed, in airship practice, when maximum power per unit of weight is necessary, I believe the tendency is toward the multiplication of cylinders, even up to eight, twelve, and more, as exemplified by the Antoinette motors. The conclusion that the "six" needs 50 per cent. more care and 50 per cent. more repair bills than the "four" is arbitrary and unjust. The 15,000-mile non-stop record of the Rolls-Royce, the 24-hour record of Mr. Edge in the Napier, and the work of the Hotchkiss may be instanced as pretty fair examples of the reliability of the six-cylinders. The absence of vibration, the constant pulling effort and the dividing of the power into a succession of surging impulses instead of instantaneous shocks rising immediately from zero to maximum so reduces the destructive effect on the entire machine, including not only the engine itself, but also the transmission, frame, body, and tires, that repairs on well-made six and eight-cylinder cars are reduced to a minimum.

The criticism of Mr. Stearns in regard to the excessive length of hood needed for some six-cylinder motors is well taken. However, if an engine is built with eight cylinders, four on each side, 90 degrees apart, it need have no longer hood than many "fours." An engine of this type is almost as far ahead of a "six." In regard to flexibility, as the "six" is ahead of the "four," and as it is a very substantial engine and still light, it may be seen a good deal more of in the future. Although most racing cars are of four cylinders, as Mr. Stearns says, still the fastest time in the world for two miles was made by an eight-cylinder machine of this type.

Carburettion troubles, instead of being increased by the multiplication of cylinders, are practically eliminated in an engine of this type, as suction is so constant as to prevent the irregular action noticeable in four-cylinder engines from different piston speeds, and the sudden cessation of suction at the end of each stroke. This arrangement of the cylinders also lends itself to intake piping of simple and symmetrical form, allows of a crankshaft similar to a four-cylinder one, needs only one camshaft, and brings the center of gravity of the motor and machine very low.

On the whole, Mr. Stearns' most valid objection to the six-cylinder machine seems to be on account of the long wheelbase, and if this can be overcome, and if, at the same time, it is possible to get greater flexibility and greater wearing qualities and reliability, will he still object?

A. G. BROOKE RIDLEY.

Alameda, Cal.

**REAL CHAMPIONS OF THE AMERICAN INDUSTRY.**

Editor THE AUTOMOBILE:

[199.]—I have read in one of the daily papers that Chairman Jefferson DeMont Thompson, of the A. A. A. racing board, has just placed an order with the E. R. Thomas Motor Company for a racer for his own personal use. If this is true, let all patriotic Americans take their hat off to him, as one of the real champions of the American industry among the wealthier sportsmen.

We have had several millionaire sportsmen, who incessantly talk of their intense interest in the welfare of the American industry, and who have established some of the largest existing tours and races, in order, as they say, to stimulate the American manufacturers and give them a chance to win; nevertheless, these self same men, after making these impressive speeches, take the first steamer to Europe and purchase two or three more foreign machines, even bringing back foreign racers to enter in their own races against American cars. Would they do this if they were sincere? If they were, would they not place their orders with American manufacturers, to help them in their struggle to gain the first rank which foreigners have been holding for years?

It is true we have had a few of these good sportsmen, probably the most prominent of whom is Dr. Harold E. Thomas, of Chicago (who owned the "Locomobile" that made such a wonderful record in the 1905 Vanderbilt Cup race, and thereby proving that at least one American manufacturer could turn out a car that was the equal of the best of the foreigners, if not better), but how few and far between have these men been. Therefore, every patriotic American ought to rejoice that Mr. Thompson has taken up the "good cause," and let them hope that a few of our wealthy sportsmen will follow his excellent example.

AMERICAN WHO WOULD, IF HE COULD, BUT CAN'T.

Boston, Mass.

## ACROSS THREE CONTINENTS BY AUTOMOBILE

AT the end of February, or early in March, a group of automobiles will start from Times Square, New York City, bound for Paris via Bering straits and the Continent of Asia. The Parisian journal, *Le Matin*, past-master in the art of organizing world-stunning performances, originated the unique contest and immediately obtained the co-operation of the *New York Times* in the realization of the idea. Although the *Matin* has had exceptional experience in organizing sporting events for its own and the public's benefit, such efforts as making the French army march, running an automobile tour around France, sending a fleet of motor boats from Algiers to the bottom of the Mediterranean, and finally the successful automobile run from Peking to Paris appear trivial compared with the scheme on which it and the *Times* have now set their journalistic hearts.

New York-Paris has only been made possible by reason of the successful termination of the Peking-Paris run, and although one may object to the shrillness of *Le Matin* trumpet and prefer fewer "Lisez *Le Matin*" posters, the journal must be congratulated on having proved the impossible possible and for displaying more faith in the automobile than the most enthusiastic automobilist. Five automobiles and one tricar started on the run across Asia and Europe, three of the cars finishing without difficulty, one straggling home very late, and only the tricar being left to whiten its bones on the desert.

To the tremendous difficulties of the 1907 run are added the hardships of crossing the Arctic regions with no other aid than the contestants can mutually grant. Providing, however, that adequate arrangements are made for supplying fuel and supplies along the route of march, there is no reason why the tour should not be successfully accomplished by a good percentage of the starters. The essential is that courageous and resourceful drivers should be selected, and that the machines should be specially constructed and equipped for the difficulties they will have to encounter. Greater road clearance, provision against cold, exceptionally low gearing, special wheels for traveling over ice, portable bridges and the best arrangement of supplies to gain space and weight are some of the matters that will have to be carefully thought out. Lessons learned from the Peking-Paris

run are that while the stores of each competitor must be so complete as to make him self-sufficing in the most complete isolation, weight must be reduced to a minimum. It is important, too, that the contestants should be bound to keep together, at any rate until European centers of civilization are reached. The natural desire to push ahead of slower competitors, dangerous in the Peking-Paris tour, might be fatal in view of the greater physical hardships of the Arctic regions.

Particulars of the route have not yet been definitely announced, expert opinion still being sought as to the most suitable way of reaching Alaska and crossing the Bering straits. It has been tentatively announced as New York to Chicago, then northward into Canada, following the line of the Canadian Pacific Railroad to Vancouver; or the run may continue across the United States through St. Louis and Denver to San Francisco, then up the coast through British Columbia to Alaska, across the Bering straits, then through Siberia to Moscow, from which point the route will be that followed by the Peking-Paris travelers. Total distance will be about fifteen thousand miles.

In France the round-the-world tour has been received with enthusiasm, Marquis de Dion, whose two cars finished in the Peking-Paris run, already declaring that he has ordered the construction of special machines for the event. Paul Lacroix, American agent for the Renault firm, who has just returned from Paris, announces that the Renault Brothers have fully considered the scheme and are decided to put in a car. Other announcements have not yet been made, but it is certain that a representative group of foreign cars will be obtained. America will not be behind, the Hol-Tan company having already made a formal entry, and Thomas and Franklin announced keen interest in the event. As a demonstration of the ability of American cars and American drivers to stand up under the greatest strain ever imposed on man and machine, no better event could be found than the run to Paris. The event will be one which will attract not merely local but world-wide attention, and American manufacturers have too much at stake to allow themselves to be outnumbered at the starting line, or to line up a team in Times Square less suited for the strenuous test than their foreign rivals.

## NO DIFFICULTIES WITH ALCOHOL AS FUEL

PARIS, Nov. 25.—An interesting statement regarding the possibilities of alcohol as fuel was presented at the conference being held in Paris during the Salon, by Eugène Brillié, designer of the 140 motor buses in use in this city. Since 1900 it has been known that both pure and denatured alcohol could be used for internal combustion engines with satisfactory results, but it has been left to the Paris municipal omnibuses to publicly demonstrate its value. The service was inaugurated on June 11, 1906, and up to date 2,231,000 miles have been covered entirely on 50 per cent. denatured alcohol. In his report M. Brillié stated that they had noted no cases of erosion or pitting of the valves, a defect which has often been attributed to alcohol, and the engine certainly heated less than with gasoline. One drawback of alcohol was a certain difficulty in starting the motor during cold weather, but this could always be overcome by passing a little gasoline through the petcocks. Their experience was that alcohol was just as effective as gasoline, the only question to be considered in its use on commercial lines being the cost of operation. In Paris gasoline cost 56 francs the hecoliter, 20 francs of which was town duty; denatured alcohol cost 39 francs per hecoliter, 5 francs 10c. of which was town duty; the difference in favor of alcohol was thus 17 francs per hecoliter. He estimated that by the use of

alcohol a saving of \$60,000 had been effected since the inauguration of the municipal omnibus service. Outside Paris the monetary advantage of alcohol was but slight, owing to the lower price of gasoline consequent on the abolition of the *octroi*.

### FARMERS CAN SUPPLY DEMAND FOR FUEL.

Reporting on the use of small alcohol stills in France, Consul-General Robert P. Skinner, of Marseilles, says that the distilling process is an exceedingly simple one and that it is possible with a mechanical outfit constructed according to the best modern experience to produce an alcohol of sufficiently high proof to be utilized for light, heat and power from such material as damaged wine and the pulp of grapes, apples, pears, etc., from which the juice has already been extracted. There is no reason either why the cheap stills on the market should not produce alcohol of even greater strength than 90 degrees if required. At present the French farmer is only interested in *eau de vie* of 50 to 70 degrees alcohol strength, but could produce a grade of greater strength if there were a demand for it for industrial purposes. Whether equal results could be obtained from potatoes and grains has yet to be proved. Automobile fuel is available if encouraged.

## TWO-CYCLE ENGINES AND ALCOHOL AT SALON

PARIS, Nov. 25.—For the more pronounced departures from the beaten track of automobile design, it is necessary to leave the gorgeous Grand Palais and plunge into the busy hall of machinery on the opposite side of the River Seine; here the many problems connected with commercial vehicles have been tackled, two-cycle and rotary engines have been developed, and alcohol is shown to be reliable as automobile fuel.

More attention than ever before is given to the use of denatured alcohol as fuel, the Automobile Club of France interest-

ELEVATED RADIATOR AND PLATFORM ON TURGAN TRUCK.

ing itself in the subject and having its own stand, designed to point out what has already been done in the matter of alcohol as a fuel for existing internal combustion engines. Progress is shown by its employment on the 140 motor buses equipped with Eugene Brillie motors, now in circulation on the streets of Paris. At the A. C. F. laboratory eight different motors, comprising a De Dion, Panhard, Dietrich, Aster, Peugeot, Tony-Hubert, Abeille, and Gillet-Forest are being run regularly with either pure or denatured alcohol as fuel.

Although the commercial position of the two-cycle engine is still very feeble in France, its standing in the technical quarters has been enormously increased. Tony-Hubert, Ixion, René Legros, Peugeot and Mietz & Wiess, all show two-cycle engines, several of them being in motion with gasoline and kerosene. Interest in this type of engine has been considerably increased of late by the efforts of the A. C. F., which has just held a competition at its laboratory. Most distinctive of all at the Salon is the Burlat rotary engine, two models of which are shown, one of 12-16-horsepower with four cylinders, and an eight-cylinder model developing 30-40-horsepower. All cylinders, which are air-cooled, rotate with the crankshaft, ignition being effected by the tops of the plugs coming into contact with an arm extending from the chassis, which conveys the high-tension current as each cylinder makes its connection in passing.

The feature of the industrial section is the showing of vehicles designed for special classes of work—as compared with standard chassis fitted with a commercial body.

Delahaye shows an automobile fire engine driven by a four-cylinder motor and operating a Delahaye-Farcot pump. Provision is made for carrying twelve men, ladders, and over 800 yards of piping. A good feature is the mounting of the hose lengths on reels hung to the frame between the road wheels. Several of these vehicles have been adopted by the Paris municipality. Dietrich also shows a fire engine designed specially for use in rural districts, driven by a four-cylinder engine and capable of delivering from 400 to 1,000 liters of water a minute. A larger model, with a 35-horsepower engine, will throw 2,000 to 2,500 liters a minute, only three men being required in the operation. This model has been in use for the past year at Nancy.

Agricultural interests are cared for by one firm only, Turgan & Rusinol, with a 50-horsepower tractor for plowing, and an automobile reaper. The plow is an original construction with three driving wheels, two of which are also steering, fitted with three speeds forward and reverse. The reaper, in addition to its ordinary work in the field, is designed to drive any fixed machines by means of belt connection.

Turgan appears to have solved the question of accessibility in rather an original manner. On one of their heavy trucks the engine is carried forward between the two side members, and two feet above it, supported on four columns running up from the side members, is the driver's platform with the radiator hung on the front of the dash. By removing the two side and the front plates the motor is rendered as accessible as on a shop bench. The arrangement necessitates some changes in the steering gear and in the water piping and pump, but is an excellent design for securing engine accessibility.

About half a dozen different types of tipping trucks are shown, fitted with metal bodies for coal, dirt or stones. On the Orion truck the tipping is performed by means of levers operated by the driver while at his steering wheel. Most of the others have adopted a worm gear by which a five-ton load can be dumped out by one man.

In the light delivery vehicle class one of the most original chassis is the Roval, particulars of which have been published in *THE AUTOMOBILE*, and which is now illustrated. Briefly, it consists of a single-cylinder motor with its gear set and transmission shaft placed transversely in the frame just forward of the rear axle, and driving the rear wheels through short side chains. A high metal platform above the power plant provides a seat for the driver, while leaving the engine and transmission perfectly

ROVAL LIGHT DELIVERY CHASSIS, WITH ENTIRE POWER PLANT OVER REAR AXLE.

BERLIET HAS FULL ELLIPTICS, SHAFT DRIVE, DROP FRAME.

accessible. Steering is by rack and pinion with connection to the front wheels. The principle is good in that it gives the maximum of space for carrying loads, but it is hardly possible to use it for anything bigger than a two-cylinder engine.

Belt transmission on a five-ton truck is decidedly novel at this stage of development, yet one such is to be seen at the Salon. A two-cylinder horizontal engine developing 12-15-horsepower transmits by a crossed belt to a transverse gear box providing four speeds forward and reverse, final drive being by roller chains to the rear wheels. Instead of a clutch a belt shifting arrangement is provided. The Pantz proved its reliability by covering 1,200 kilometers during the fifteen days of the French army maneuvers without any adjustment.

In the small runabout class—or as the French prefer to call it, *voiturette*—a new and distinctive type of vehicle has been developed, which if put on a sound commercial basis should give the French a new lease of life in the automobile world. Unfortunately in the majority of cases the small cars, though excellent from a mechanical standpoint, are not produced by firms with sufficient commercial standing to give them more than a local success. There are a few exceptions, as in the Lion-Peugeot, Werner, Darracq, and Sizaire-Naudin, but the majority are likely to go down for want of financial backing, or to find their efforts exploited by outside moneyed interests.

Prominent among these little vehicles listed at prices varying from \$500 to \$1,000, is the Sizaire-Naudin, typical of its class in having a single-cylinder vertical motor forward under a bonnet, but distinctive in several features of engine design and transmission. As in all these models, a pressed steel frame is employed, with the car well suspended and hung low to give a smart, racy appearance. The Sizaire-Naudin is distinctive in having a transverse front spring, though in the majority of cases the *voiturettes* have semi-elliptics in front and platform type or three-quarter elliptics in the rear. The power plant consists of a high-speed

NEW MODEL OF FOUR-CYLINDER CHAIN-DRIVEN CHARRON.

single-cylinder motor 4.7 bore by 4.3 stroke, water-cooled, with mechanically operated valves, the intake being immediately above the exhaust valve and operated by a rocker arm. Motor control is entirely by variable intake valve, the inlet valve cam being movable on its shaft by means of a lever fixed on the steering wheel. Ignition is by high-tension Simms-Bosch magneto with fixed sparking point. Thermo-syphon water circulation is employed through a tubular radiator without fins, surmounted by a large capacity water tank.

In both clutch and transmission the Sizaire-Naudin has distinctive features, excellent because of their simplicity and consequent low price of production, and their reliability as shown in tests. A special type of disk clutch is employed, and the gearbox and differential are contained in a single housing on the rear axle.

In the majority of the *voiturettes* standard lines of construction have been followed more closely, the machines being but miniatures of large touring cars, with such standard features as disk clutch, sliding gear transmission and shaft drive. There is one case of a selective transmission on a single-cylinder car, and a single case of transmission by friction disks; planetary transmission, too, has one supporter. Lion-Peugeot is distinctive in employing side chains for final drive for both the two-cylinder and single-cylinder machines. Side members and body in a single stamping, which offers considerable attractions for a cheap production, has not found the number of supporters expected of it. Darracq has adopted this type of construction for the new single and two-cylinder models, and some examples of this type of construction are found on the metal-workers' stands, but it does not appear to have been adopted by other constructors. The accepted principle appears to be to stamp out one seat with each side member, uniting them together when the frame is built up with the cross members. The construction is one of the strongest possible, can easily be upholstered, and allows of enameling instead of painting and varnishing; its cost, too, is low.

## WHAT AMERICAN VISITORS SAW AT LONDON'S BIG SHOW

By ALFRED REEVES, GENERAL MANAGER, AMERICAN MOTOR CAR MANUFACTURERS' ASSOCIATION.

LONDON, Nov. 18.—Two Americans direct from the New York shows can hardly visit a big exhibition like the one now in progress at the Olympia without observing many new things and being impressed in particular with the importance of American makers sending their representatives to the English and French shows. While there are many things we can teach the foreigners, especially in the matter of general appearance and method of marketing, we can also learn a great deal from our English cousins. This much was proven to me beyond argument after a week at Olympia in company with Howard C. Marmon, the designer of the Marmon car and a member of the technical committee of the American Motor Car Manufacturers' Association.

The exhibition here is for two weeks, and there is a decided difference of opinion as to the worth of so long an affair. Most exhibitors declare one week to be enough. The automobile makers have decided against many of the opposed local shows, declaring in favor of one big exhibition, just as American makers favor. There is a little talk of giving up shows, but very little. Olympia has been taken again for two years as the place for shows here. It is generally agreed that nothing would be more harmful than a failure to hold the annual exhibition. The attendance at Olympia has run from fifteen to twenty thousand a day.

No one can visit the 140-car exhibits at this show without being impressed with the dominating influence of the small car. It is seen everywhere on the streets and apparently is taking the lead. The favored types seem to be those of four cylinders of from 10 to 20 horsepower, with a seating capacity of four. There are some students of auto building here who declare the car to make now is either a small one for the man who does not have a chauffeur, or a very large one on which a chauffeur is absolutely necessary.

I was very glad to see a feeling of conservatism in the trade, without pessimism. It is generally agreed that a little toning down of business is necessary and will be beneficial, but our English friends say they cannot see where there is going to be any great falling off in trade. Nevertheless they have discounted a good portion of any falling off by a general reduction in prices, averaging about 25 per cent. This is rather a big cut, and it applies pretty generally. The makers believe it warranted by the large production of cars and a lower cost of manufacture.

Olympia show is twice the size of anything held in America. The stands are all individually decorated, supplying a novel effect though of course rather costly. Next year will see uniform dec-

orations for the building and the stands, just as we have in America. There are four American cars shown—the Ford, White, Cadillac, and Buick. There was always a crowd at the Cadillac, which has a good reputation here, and at the White stand, for the steamer has been unusually successful in England. Those Americans who were here had the first opportunity along with other visitors of seeing the Ford line, and, as might be expected, the low prices create a sensation. The new four-passenger light touring car and the taxicab or town car were constantly surrounded by visitors. Among a score of other things which Americans would notice at the show were:

- Every stand showing a shaft-drive car except Mercedes.
  - Entire lack of runabouts with rumble seats, except the Buick.
  - Adjustable foot pedals.
  - Tubular front axles even on heavy cars.
  - Many advances in coach work.
  - Almost total disappearance of the cone clutch.
  - The appearance of a couple of buggysabouts.
  - The increased use of the motor as a brake.
  - Lack of interest in self-starting devices.
  - A growing practice of abolishing the spark adjustment on the wheel.
  - An unlimited fancy in radiator designs.
  - General cleaning up of dashboards.
  - Change in the carbureter, locating the auxiliary air valve from the manifold.
  - A tendency to lengthen rather than shorten wheelbase.
  - The use of three bearings on transmission shaft.
  - Increased use of shock absorbers as general equipment.
  - Ratchet sprags on transmissions.
  - The fastening of crankcases without the use of arms.
  - Three-quarter elliptic springs on the rear.
  - Grease cups on ball-bearing steering joints.
  - Hand adjustment of brakes.
  - Thermo-syphon system of cooling on town cars.
  - Casting of four cylinders in one on small cars.
- London itself is a city of automobiles, ranging from the motorcycle to auto drays, carrying loads of coal. There are 800 taxicabs in successful operation in the streets and 200 or 300 motor 'buses that are having a hard time standing up under the terrific trials they have to go daily. The roads around England call for enthusiasm from the American, for they are simply ideal. Among the Americans at the show this week were noticed Walter C. White, Russell Huff, and Howard Coffin.

## FIRST IMPRESSIONS OF FRENCH DECENNIAL SHOW

By ALFRED REEVES, GENERAL MANAGER, AMERICAN MOTOR CAR MANUFACTURERS' ASSOCIATION

PARIS, Nov. 23.—Though the London show was a great automobile event, the Paris Salon eclipses it and is certainly the finest thing of its kind the world has ever seen. The thousands of lights under the roof of the Grand Palais make up a decorative scheme which is par excellence, and the automobiles on exhibit comprise the finest constructions in the world. One feature of the exhibition is the great foreign demand for low priced and medium priced cars; while in some respects the foreign cars are superior to those constructed in America, in the medium priced class we are equal to if not better than the foreigner. There is no dearth of enthusiasm here among the automobile purchasing public, and sales will certainly equal those of last year, especially in medium priced cars. All Paris is alive with the Salon, the show being organized on such a scale that it is impossible for any individual to be unaware of its existence. During the busy

hours of the afternoon the crowd is so great that at times further entries have to be refused. To judge from the crowds in the Champs-Elysées on Sunday, all Paris is bent on seeing the show.

### FORD PLACES AN EXCLUSIVE FRENCH AGENCY.

PARIS, Nov. 25.—Henry Depasse, one of the best known of French sportsmen, who in the bicycle days won fame under the name of Dary, has obtained the exclusive agency for France of Ford runabouts. A few years ago Depasse founded the Elysée Automobile Palace in the Avenue des Champs-Elysées, and it is here that the American runabout will be shown. The little four-cylinder car will be marketed in France at \$780. Other American firms having agencies in Paris are Oldsmobile, represented by H. de la Fresnaye, and Mitchell with a garage in the suburbs.

**Certainty of Sounder Health in Auto Industry.** There are some men who are so constituted that they gaze out upon the world through a thick and mournful haze, as it were. To them every cloud is a black one and every omen one portending evil to come. In common with all others, the automobile industry has its share of these pessimists and calamity howlers, and probably it always will, but it is doubtful if they will always be granted the opportunity to give vent to their dolorous wailing at the expense of the industry that supports them, as has been the case during the past half year or so. The inexorable law of the survival of the fittest will make its influence felt no less surely in their case than it does in that of others, although the process may be a slow one.

To any one who will take the trouble to look beneath the surface it must be evident that there is really less reason for indulging in a streak of pessimism regarding its future than there ever has been during its short but marvelous career. As an industry that has catered almost exclusively to the man who invests for pleasure alone, it has suffered less from the recent financial depression than any other similarly situated, and, all things considered, the outlook for a successful business year during 1908 could not be improved without changing the face of things in general.

It must be borne in mind that, unfortunately, the recent slump took the industry at its worst—at a time when it was going through a period of transition, passing from the status of the “automobile game” to that of a well-settled business in which

the great big hip, hip, hurrah style of proceeding will no longer figure prominently. Then why not take things at their par value and realize that, while there may be a portion of the industrial body diseased, it is rapidly being cut away and that the eventful result will be sounder health in the automobile business than has ever before prevailed. Dyed-in-the-wool pessimism never helped anybody or anything, and never will.

**Changing Standards of Automobile Suspension.**

There have been two epochs, so to speak, in the history of the American automobile. The first, in which design and development were entirely in accord with purely American ideas and long independent lines—in short, a period in which foreign ideals were looked at askance, and the average American builder was determined to evolve a distinctive type of his own. The second, in which these ideals were thrown overboard and foreign standards closely patterned after. In common with other features of design, the suspension has changed with the varying standards followed. Primarily, the American car closely followed the carriage maker’s idea of springing and double-elliptic springs were common. They gave way later to the long semi-elliptic with its new methods of placing and attachment to the frame that the continental designer had introduced, and now it is noticeable that there is a more or less general reversion to former standards for reasons that are not hard to understand. The semi-elliptic spring is extremely sensitive, but its range of action is correspondingly limited, and this fact was responsible for the creation of the now familiar shock absorber, for the semi-elliptic is not capable of absorbing unusually heavy shocks, particularly when they follow one another quickly. To overcome this, foreign designers have increased the length of the spring until it now measures a third or more of the length of the frame, and while its sensitiveness is correspondingly enhanced, and its “good road” action proportionately improved, its adaptability to rough road work is not such as to make it the equal of the full-elliptic spring, which is again coming more and more into vogue with the American designer. The platform type of suspension is likewise finding renewed favor, on the part of both foreign and American designers, though it will be recalled that both have tried it and abandoned it in earlier days. Where the American builder is concerned, it is merely a case of coming to a realization of the fact that what is suitable for the good roads of the Continent is out of place on their American counterparts, and designs must be altered accordingly.

**The Plain Truth and a Certain Remedy.**

After a close study of the features of the present financial disturbance, the American Trade Press Association has arrived at the gist of the matter in the following resolution, which, among others, was adopted at a special meeting of the Association:

That the so-called business depression is due principally to a want of confidence which is unwarranted by agricultural and industrial conditions, and that one of the worst results of the panicky feeling that prevails is the hoarding of money, in which many banks are principal offenders—many holding much more cash than the reserves called for by the banking laws, and setting a most hurtful example to individuals.

Official figures are not wanting to prove the soundness of the Association’s summing up of the situation. They are found in the \$1,434,000,000 imports during the fiscal year of 1907, compared with \$1,227,000,000 during the same period of 1906, and \$765,000,000 in 1897; in increased exports from \$1,718,000,000 to \$1,854,000,000 during the last financial year. Records for production are equally satisfactory: thus for 1906, the last year for which figures are available, pig iron had increased 2,000,000 tons during the twelve months; petroleum production was 5,333,000,000 gallons against 2,500,000,000 a decade earlier; the number of cotton spindles in operation in mills of the Northern States was 15,666,000 against 13,900,000 in 1897; in the Southern States the figures for the same relative periods are 9,000,000 and 3,250,000.

## VANDERBILT CUP RACE TO BE HELD IN 1908

THERE will be a race for the William K. Vanderbilt, Jr., Cup in 1908. Exact date and location of course may not be announced before July 1, though conditions may make possible earlier publicity. At any rate, a race will be held, and the manufacturers may count upon the event for October next.

After the executive committee of the A. A. A. Racing Board had had a session on November 27 at A. A. A. headquarters, No. 437 Fifth avenue, and disposed of many routine matters, it resolved itself into a meeting of the Vanderbilt Cup Commission. Recognizing the need of an early announcement, it was decided to take the bull by the horns and decide upon the holding of a race for the cup in 1908, assurances from various sources justifying the commission in reaching its decision.

The official announcement contains these facts, though the rules will be given further consideration before being made public:

Competition for this cup, under the terms of the deed of gift, is open only to clubs that are recognized by or affiliated with the American Automobile Association, or to clubs likewise related to the Automobile Club of France, and not more than ten cars can represent any one competing country. No car shall be allowed to compete for this cup whose weight shall exceed 1,100 kilos, or 2,424.4 pounds, instead

of 1,000 kilos, or 2,204 pounds, as heretofore, and must carry two persons seated side by side, whose weight must not be less than 132 pounds each. Each car must be manufactured in its entirety in the country which it represents.

The club winning the trophy is obligated to deposit with the American Automobile Association a bond of not less than \$3,000 for the safety of the cup. The entry fee will be \$1,000 for each car, which covers the elimination and final events, and entries received after the closing date, September 1, 1908, and before October 1, 1908, will be doubled, making the fee \$2,000. No entries will be received after October 1, 1908. The race shall be for not less than 250 miles, nor over 300 miles.

Before taking up its duties as the Vanderbilt Cup Commission, the board unanimously adopted this resolution:

Resolved, That it is the sense of this meeting that the Racing Board approve the sportsmanlike action of the Automobile Club of America and the Florida East Coast Automobile Association, in their endeavor to resuscitate high class racing on the Ormond-Daytona Beach; and further, we assure both clubs of our hearty and earnest support.

Present at the meeting were Jefferson deMont Thompson, chairman; Dave H. Morris, Frank G. Webb, A. R. Pardington, A. G. Batchelder, A. L. Riker, technical advisor; Frederick H. Elliott, secretary.

### A. A. A. ANNOUNCES TECHNICAL BOARD.

Announcement has been made by President William H. Hotchkiss, of the American Automobile Association, of the appointment of the new Technical Board of that body. Waiving his right to nominate the members to the president for appointment, Chairman N. H. Van Sicklen requested President Hotchkiss to select such persons as he thought were best qualified to perform the work of the Technical Board, the appointments being, therefore, with the exception of the present technical advisors of the Racing Board, E. R. Thomas, A. L. Riker, and Henry Ford, largely the nominees of the various State associations. The composition of the board is as follows:

N. H. Van Sicklen, Chairman, Chicago.  
 David Beecroft, Chicago.  
 H. O. Smith, Indianapolis, Ind.  
 Edgar Apperson, Kokomo, Ind.  
 Walter C. Baker, Cleveland, Ohio.  
 Henry Souther, Hartford, Conn.  
 S. N. Colburn, Minneapolis, Minn.  
 E. R. Thomas, Buffalo, N. Y.  
 Clarence E. Whitney, Hartford, Conn.  
 E. T. Birdsall, Rochester, N. Y.  
 Angus Sinclair, Newark, N. J.  
 J. C. Kerrison, Boston.  
 Henry Ford, Detroit, Mich.  
 H. M. Rowe, Baltimore.  
 A. C. Newby, Indianapolis, Ind.  
 A. L. Riker, Bridgeport, Conn.  
 Roy F. Britton, St. Louis.

It is quite probable that the present membership of seventeen will be increased by nominees from the affiliated clubs and State associations. David Beecroft, of Chicago, has been suggested by President Hotchkiss for the post of secretary and vice-chairman. The first meeting of the board will be held at Chicago on December 6, when it is expected that plans will be laid for a number of technical contests in different parts of the country during the coming season.

The French Minister of Public Works has called a conference to be held in Paris in November of next year, to consider road question developed as the result of the growth of automobile traffic; new methods for new conditions will be the theme of the gathering. The Touring Club of France and the national automobile club are taking an active part in the organization of the meetings, delegates being expected from all countries.

### EUROPE OUTLINES A FULL PROGRAM.

PARIS, Nov. 25.—Dates for the most important European automobile events were decided upon at the calendar congress held at the A. C. F. temporary clubrooms in the Grand Palais and attended by representatives from all European automobile associations and organized bodies. The congress, the third annual one held in Paris, is intended to mark out as near as possible the sporting program for the year without clashing of interests. From January 18 to February 2 the Automobile Club of Italy will hold its international exhibition. Events in March will be the automobile week at Nice and a number of local contests in the south of France. Monaco motor boat races have been fixed for April 1 to 13, followed by yachting and cruising events, and on April 25 the French commercial vehicle tests will commence, ending exactly a month later. Important meetings in May will be the Targa Florio on the 10th and the Moscow exhibition. The Royal Automobile Club of Great Britain has fixed on June 1 to 18 for its reliability trials. During the first fortnight of July—the exact date has not yet been decided on—the Automobile Club of France will hold its Grand Prix race, probably at Dieppe. Ostend races will be run off from the 13th to 17th and races on the Ardennes circuit for racers and touring cars will occupy July 20 to 30.

The Coup de la Presse in Normandy, Ostend motor boat week, Evereaux speed tests, Paris-to-the-Sea motor boat race, Salon straightaway tests and Mont Ventoux hill climb will be the outstanding features of August. During September *L'Auto* will run the voiturette race, motor boat races will be held at Arcachon and the Italian clubs will organize commercial vehicle tests. Near Paris motor boats will race on the Seine and all classes of cars will climb Chateau-Thierry hill. October events are the Gaillon hill climb in France and the Royal British clubs only speed test under limited cylinder rules.

At the international conference of automobile clubs, attended by representatives from all countries but America, an international formula for touring car competitions was referred to a special committee. What to do with two-cycle engines and those of the Gobron type in races under the international 155 millimeter rule was settled by leaving the formula to be adopted by the technical committee of the A. C. F. Complaints were received from drivers on the danger to eyesight from the present system of tarring race tracks. The next meeting is announced for Paris in May.

## "MOTORING" MORGAN SHOULD ASK MR. MORRELL

BY AN A. A. A. MEMBER.

ONCE upon a time the auto department of the New York *Globe* contained news matter. Nowadays it serves principally as an avenue for "Senator" Morgan to vent his spleen upon the officials of the American Automobile Association, possibly because the New Jersey Automobile and Motor Club, of which he was once a prominent member, does not designate him as one of its directors to the State association and also on the national board of directors. Herewith is a recent sample of what the "Senator" considers "news" for *Globe* readers:

"The question whether the membership of the American Automobile Association would approve the spending of their money in a race meet speculation is another matter, but they were not consulted in the Morris Park meet in 1908, of which there has never been any definite financial statement made. If the A. A. A. is to enter the lists as a promoting body it would seem that it should first consult the membership of the association, as running race meets is not altogether a financial certainty, unless it happens to be a Vanderbilt road race, which was made a success before the A. A. A. took hold of it."

In view of the fact that the Morris Park meet referred to was conducted in July, 1905—not—1903—when Robert Lee Morrell was chairman of the A. A. A. Racing Board, Alfred Reeves, the manager of the track, and Dave Hennen Morris, president of the Morris Park Motor Racing Club, the suspicious "muck-raker" of automobilism is referred to these three for "facts," which when printed should prove as great a "mare's nest" as the well-meaning but erratic "Senator" has unearthed in other directions. By all means have the financial statement made public.

While the successful conduct of all organizations requires the election of directors and the delegation of power to them, it might be that if the entire membership were consulted by a referendum on all questions the transaction of business would be facilitated. But a majority seem to hold to a contrary opinion. In support of this is the recent acquiescence of Automobile

Club of America members (who were not consulted) in accepting as a matter of course the action of the club's governors directing the contest committee to take complete control of the 1908 Ormond-Daytona races, though Florida papers recently stated that "Motoring Morgan is in full charge of this tournament." When the A. A. A. Racing Board was some time ago approached by ex-President Asa Paine, of the Florida East Coast Automobile Association, looking forward to the adding of the Florida meet to the two other A. A. A. national fixtures—Vanderbilt Cup race and Glidden Trophy tour—one condition insisted upon by the Board was that it should have a free hand, unannoyed by any "tournament manager." Realizing that meager profits—if any—could not now be expected from two Florida races, the Racing Board's consideration of the matter was actuated simply by a desire to give makers, and also amateur opportunity of competing under assured conditions. With F. E. C. A. A., even though it were through the clever manipulations of "Motoring" Morgan, accomplishing an arrangement with the A. C. A., that solution found ready acceptance by the national organization, which will assist its biggest club member in whatever way it can to insure a success, it being positively announced by the club that it alone has charge of the affair.

"Motoring" Morgan's reference to the Vanderbilt race is as erroneous as his other statements. The A. A. A. Racing Board, the executive committee of which constitutes the Vanderbilt Cup commission, has conducted the three cup races held thus far, and therefore it couldn't have been "made a success before the A. A. A. took hold of it." With A. R. Pardington, the chairman in 1904; Robert Lee Morrell, in 1905; and Jefferson deMont Thompson, in 1906, the race has been in capable hands, as it will be again in 1908, with Mr. Thompson as chairman and Mr. Pardington a member of the board, to which Mr. Vanderbilt also belongs.

## AN ARTISTIC SETTING FOR IMPORTERS' SHOW

FOR the decorative scheme of Madison Square Garden during the Importers' Salon, opening December 28, the artist in chief has set himself the task of reproducing a scene on a fête day in the Avenue des Champs-Élysées, Paris. Although the illusion as shown by the designer's sketch is not very convincing, a decorative scheme appears to have been adopted worthy of the artistic home of most of the coming tenants.

The floor plan of the Garden has been so altered for the Importers' Salon that there will be a wide aisle down the center

parallel to which and on either side will be two other aisles. The same amount of floor space will be available as before, but without the impediment of overhanging balconies and other obstructions. On the ground floor will be housed all the car exhibits, the platform encircling the arena and the mezzanine floor just above it being given over to the accessory exhibits. The top gallery will serve as a spectators' gallery and as a café, the gallery at the Fourth avenue end, usually set apart for visitors, being occupied entirely by the large canvas mural decoration.

Entrance to the Salon will be from the foyer through a Louis XIV gateway with a canopied ceiling, into the refined beauty of the ivory and blue hall. Entrance to the main aisle will be through a semicircular façade adorned with electric lights. In the center of the hall a sculptured group will be erected, the main figure of which will embody the "Spirit of Speed" delineated in "Pal's" advertising poster of the Salon, the same motive being adopted in the decoration of the gateway and the panels. At the extreme Fourth avenue end the central aisle will terminate in a fountain more than thirty feet in height, on each side of which will be a peristyle of columns capped with glowing lights.

There will be no exhibition in the concert hall, this part of the building being intended as a real garden in which natural flowers and palms are promised and where wicker chairs will invite the weary to rest. On the top gallery of the main hall visitors may lounge and sip coffee and, in imagination at least, enjoy the gay scene of the Champs-Élysées in its gayest and choicest setting. S. R. Ball, the well-known decorator, will prepare the Garden for its imported tenants and American visitors.

HOW THE BIG GARDEN WILL BE DRESSED FOR THE IMPORTERS.

PISCHOFF AEROPLANE, DRIVEN BY ANZANI MOTOR PREPARING FOR TRIAL FLIGHT NEAR PARIS.

### AEROPLANE FLEET STILL GROWING IN SIZE.

PARIS, Nov. 25.—Still another unit has been added to the aeronautical fleet of Paris, and has made its debut on the common training ground at Issy-les-Moulineaux. The aeroplane, built for M. de Pischoff by the Chauvière firm, is of the cellular type, driven by a two-cylinder Anzani motor carried forward and coupled direct to a two-blade aluminum propeller. The pilot is placed immediately behind his power plant and between the two bearing surfaces, an inclined column and automobile steering wheel giving communication with the rear road wheel and the rear cellular rudder. While running at three-quarter speed on the second day of the tests Pischoff collided with a tree while trying to avoid a group of soldiers, with the result that the rudder was smashed and one of the road wheels collapsed, the pilot being thrown to the ground without injury.

Officials of the Aero Club of France are having a busy time attending to all the engagements for the \$20,000 Deutsch-Archdeacon prize and record flights of 150 meters. Henry Farman is still favorite, for he has already practically covered the closed kilometer in practice flights, but is closely pressed by a dozen others, all training for aerial supremacy. While testing his aeroplane at Buc, Esnault-Pelterie was agreeably surprised by a visit from the *Ville de Paris*, with Madame Kapferer, among others, on board. A descent was made, greetings were exchanged, and M. and Mme. Kapferer descended, Comite de la Vaulx took their place and the aerial yacht continued its trip.

RENAULT EIGHT-CYLINDER AIR-COOLED ENGINE.

### AERONAUTICAL SCHOOL FOR NEW YORK.

Instruction in aerial science, at present confined to a few schools in Paris, Lyons and Bordeaux, is promised for all by a correspondence class to be opened in January as a branch of the New York School of Automobile Engineers, in West Fifty-sixth street, New York City. Albert Triaca, one of the instructors at the school of automobile engineers, believing that interest in aerial navigation will become even greater than that in automobile matters, has made a close study of the science and is now perfecting details for a course of instruction by correspondence which will offer all the advantages to be obtained by attendance at the European centers. With this object in view he has visited France and obtained the collaboration of some of the leaders in the aeronautical world, among them being Colonel Espitallier, vice-president of the international aeronautical commission. An important matter in the study of the science of aeronautics is that close touch should be kept with the work of experimenters; this has been arranged for in such a way that as developments are made and experiments succeed, the results will be communicated to the school and through the course to all students.

Mr. Triaca, who returns to this country shortly, will bring with him a collection of models of aerial machines, a library of aeronautical works gathered at the suggestion of George Besançon, secretary of the Aero Club of France, an Antoinette eight-cylinder motor for aerial work, and will represent such well-known constructors as Mallet and Chauvière. The course to be commenced in January will be entirely by correspondence; it is hoped, however, to give class instruction at an early date, and to arrange for ascensions, probably under Charles Levée, of the French Club.

### EIGHT-CYLINDER AERO ENGINE BY RENAULT.

PARIS, Nov. 25.—The new aerial motor produced by Renault Frères, and now shown at the Salon, is attracting considerable attention in aeronautical circles. It is an eight-cylinder air-cooled engine, with cylinders placed in V and slightly offset. The valves, all mechanically operated, are superimposed, the exhaust valves being in the cylinder head and operated by rocker arms. In the angle formed by the cylinders is the carbureter and all intake piping, and the connections to the spark plugs, each one of which is placed immediately above an inlet valve. The high-tension magneto is bolted in an inverted position immediately below a forward extension of the crankshaft. Above it is a high-speed fan drawing in a strong draught of air to the cylinder walls, the housing around the engine being designed to give the best distribution of the forced draught.

### FRENCH WAR BALLOON AN AERIAL DERELICT.

PARIS, Dec. 1.—All France is mourning the fate of the *Patrie*, finest unit of the army aerial squadron and undoubtedly the most successful dirigible balloon ever built, now a helpless aerial derelict somewhere over the Atlantic. While some repairs were being effected on her engine at Verdun, Saturday, a strong squall of wind flattened the airship down to earth and gave the 200 troopers a busy time holding onto the guy ropes. Before they could recover themselves a second and stronger squall caught the air ship and carried it skywards despite the efforts of the clinging soldiers. One by one the men dropped off, and, freed from all restraint, the balloon shot skyward and headed towards Chalons, sailing majestically, notwithstanding that the valve rope had been pulled and gas was escaping.

Automobiles immediately chased after the balloon, and telegraph orders were sent to the Atlantic naval stations to keep a lookout for the passage of the ship. The only news that was received, however, was a message from Lloyds signal station at Tarr Head, Ireland, to the effect that the *Patrie* had been seen drifting northward at the rate of about six miles an hour, and all hope of saving her had therefore to be reluctantly abandoned. The Government is considering the offer of Henry Deusch de la Meuthe to place his private airship *Ville de Paris* at the disposition of the army authorities pending the completion of the *Republique*, sister ship to the *Patrie*, now building. Indignation is strongly mixed with the sorrow at the loss of the French airship, and an official inquiry will be held to fix the responsibility for the loss. The envelope of the *Patrie* was made in Germany by the Continental Caoutchouc Company, the design, however, being the work of French engineers. German authorities are reported to have endeavored to obtain the secret of her success, but in vain. Only a few days ago the *Patrie* made a non-stop run from Paris to Verdun, her military station on the eastern frontier, covering the 150 miles in seven hours, proving as steady in a strong breeze and at a twenty-mile-an-hour gait as an Atlantic liner. Her motor is a four-cylinder Panhard.

Latest news received of the *Patrie* is to the effect that she has been seen passing over Clydebank, near Glasgow, in a north-westerly direction.

### DRAWBACK ALLOWED ON EXPORTED FITTINGS.

WASHINGTON, D. C., Dec. 1.—Regulations have been issued by the Treasury Department providing that on the exportation of automobiles manufactured by Brewster & Company, of New York, with the use of imported woolen carriage cloth, plate glass, metal fittings, metal chains, rubber tires, and other imported parts and materials, a drawback shall be allowed equal in amount to the duties paid on the imported parts and materials so used, less the legal deduction of one per cent., except in the case of leathers manufactured in the United States from imported hides, on which an allowance of 100 per cent. of the duty paid on the portion of the hides so used is granted by law. The drawback entry must show the total number of automobiles exported, the number of imported parts, chassis and tires, and the amount of other imported materials of various kinds.

### ARMY TO EXPERIMENT WITH AUTO TRUCKS.

WASHINGTON, D. C., Dec. 1.—It is stated at the War Department that experiments with a view of determining the practicability of extending the use of automobiles in the army are in contemplation by the Quartermaster General. Automobiles have been employed to some extent, such as for passenger transportation, for headquarters in the field, signal corps wagons, and ambulances. Now the army officers have in view tests to demonstrate the efficiency of motor-driven vehicles for transportation of heavy stores in the field, under all conditions to be met in the service, such as hilly country, bad roads, and long distances from sources of supply of fuel.

### NOW THE AUTO HAS INVADDED THE STAGE.

Under the name of "The Auto Race," the New York Hippodrome is running a play only possible on the immense stage with which this house is equipped. The spectacular features of the play are based on the Vanderbilt Cup race, and to the automobilist the show is interesting in exhibiting the ingenuity of the modern stage manager in overcoming the obstacle of presenting the modern vehicle in action in a public building. The opening scene shows a road on Long Island with people arriving in automobiles, sight-seeing cars, and other vehicles to witness the race. An idea of the immensity of the production may be judged by the fact that there are six White steamers, a huge electric sight-seeing car, and the three racers on the stage at one time, the latter cars being property vehicles built on the lines of the big racers. The White steamers run on the stage under their own power, and one wonders how the law against gasoline is overcome. It remained for Edwin Wakefield, the property man of the house, to solve the problem. Each of the steamers is equipped with a tank of compressed air and it is this medium which furnishes the power. The start of the race is a brilliant scene, but it lacks the dramatic ensemble of the exciting scene which early morning visitors of the real race witnessed, and a number of changes are now being made to bring the effect out stronger.

Though this is not the first time real automobiles have appeared on the stage, several being used at a Broadway theater producing "The Vanderbilt Cup," it is the first time such a large and realistic display has been attempted.

### WILMINGTON HOLDS ITS FIRST BEACH RACES.

WILMINGTON, N. C., Nov. 20.—It was at first intended to hold the Wrightsville Beach auto races, organized by the Wilmington Automobile Club, on Thanksgiving Day, but as the tide waits for no man, and the beach surface would have been impracticable at the hours desired on that day, the date was advanced to Saturday, November 23. The beach course at Wrightsville is a trifle over a mile and a half in length, and, in spite of the threatening weather, the course was well lined with spectators who saw some good sport. Four events were on the program, two of which were open to Maxwell and Ford runabouts respectively, the former being won by Frank Herbst, and the latter by J. E. Platt. The third event was between the winners of the preceding events, and was won by Mr. Herbst in his 15-horsepower Maxwell in 2:04 1-5, the distance driven being the length of the course.

The fourth event was for a mile with flying start and for a championship medal offered by George Honnet, Jr. The Maxwell runabout, with Mr. Herbst at the wheel, was again a winner in 1:23, with Fred Dock, in a Ford, second. The successful manner in which the races were conducted means that several events open to automobilists in the State will be arranged for the beach course in the near future.

FRANK HERBST IN HIS WINNING MAXWELL AT WILMINGTON.

## THREE DAYS OF AUTOMOBILE ENDURANCE.

*(Continued from page 848)*

- No. 20. Studebaker.—Points lost: exhaust cut-out repaired, 4 points; oil cup lost, 4 points; wheel belt broken, 8 points; total, 16 points. Official weight, 2,905 pounds. (Protest has been filed by local representative.)
- No. 28. Kisselkar.—Points lost: frame and engine bolt loose, 2 points; emergency brake not adjusted, 4 points; shield fastening bolt broken, 4 points; bonnet clip broken, 4 points; total, 18 points. Official weight, 2,965 pounds.
- No. 36. National.—Points lost: headlight screw loose, 4 points; muffler separated and hanging, 14 points; crank bracket loose, 2 points; gasoline tip loose and leaking, 2 points; loose lamps, 4 points; total, 26 points. Official weight, 3,100 pounds.
- No. 32. Silent Knight.—Points lost: lamps loose, 8 points; oil pipe off, 8 points; drag-link replacement on drive shaft, 20 points; joint cover loose, 8 points; work on lamps, etc., 10 points; total, 54 points. Official weight, 3,325 pounds.
- No. 2. Pierce-Arrow.—Points lost: brakes, 26 points; emergency brake, medium, 2 points; lamp loose, 2 points; seal broken, 25 points; total, 55 points. Official weight, 3,490 pounds.
- No. 11. Jackson.—Points lost: battery wire repaired, 25 points; battery dead, 4 points; steering gear loose, 8 points; strut rod work, 4 points; seal broken, 25 points; total, 66 points. Official weight, 2,700 pounds.
- No. 34. Locomobile.—Points lost: brake repair, 10 points; spring shackle work, 16 points; battery dead, 2 points; grease cup loose on jackshaft, 6 points; horn out of commission, 8 points; seal broken, 25 points; total, 67 points. Official weight, 3,690 pounds.
- No. 12. Autocar.—Points lost: work on spark plugs, 8 points; muffler, 4 points; emergency brake, 4 points; lamp, speedometer and horn loose, 2, 4 and 2 points respectively; seals broken, 50 points; total, 74 points. Official weight, 2,600 pounds.
- No. 35. Premier.—Points lost: fenders repaired, 18 points; grease cup lost, 4 points; bonnet clip broken, 4 points; replacing fenders, 46 points; fastening seat, 4 points; fastening lamp, 2 points; total, 78 points. Official weight, 2,518 pounds.
- No. 15. Dragon.—Points lost: one cylinder missing, 50 points; emergency brake, medium, 2 points; steering gear, 6 points; mud apron down, 26 points; shock absorbers, 6 points; total, 90 points. Official weight, 2,240 pounds.
- No. 9. Stoddard-Dayton.—Points lost: replacing valve spring, 82 points; broken seal, 25 points; total, 107 points. Official weight, 2,755 pounds.
- No. 24. White.—Points lost: fan blade broken, pump broken, pipe disconnected, 110 points; total, 110 points. Official weight, 3,065 pounds.
- No. 22. White.—Points lost: steering gear defective, 135 points; lamp loose, 2 points; total, 137 points. Official weight, 3,735 pounds.
- No. 8. Stevens-Duryea.—Points lost: bent front axle, 174 points; horn loose, 8 points; lamp loose, 4 points; total, 186 points. Official weight, 4,113 pounds.
- No. 16. Rapid (12-passenger 'bus)—Points lost: ignition trouble, 54 points; ignition trouble, 16 points; running board, 4 points; mud apron, 2 points; speedometer, horn and lamp, loose and broken, 12 points; broken seals, 100 points; total, 186 points. Official weight, 3,705 pounds.
- No. 5. Wayne.—Points lost: starting handle loose, etc., 20 points; broken spindle, 600 points; total, 620 points. Official weight, 2,505 pounds.
- No. 25. Reo.—Points lost: radiator trouble, 134 points; strut rod, 2 points; deck screws, 4 points; radiator, 900 points; total, 1,040 points. Official weight, 1,900 pounds.
- No. 13. Maxwell.—Points lost: engine work and running gear repairs, 734 points; wheel replaced, 77 points; fan bracket and fan down, 12 points; strut rod, 10 points; broken seals, 275 points; total, 1,108 points. Official weight, 2,122 pounds.
- No. 31. Pierce-Racine—Withdrew, third day.
- No. 6. Matheson—Withdrew, third day.
- No. 7. Matheson—Withdrew, second day.
- No. 10. Jackson—Withdrew, second day.
- No. 1. Royal Tourist—Withdrew, first day.
- No. 26. Matheson—Withdrew, first day.
- No. 17. Frayer-Miller—Withdrew, first day.
- No. 19. Marion—Withdrew, first day.
- No. 21. Thomas—Withdrew, first day.
- No. 27. Stoddard-Dayton (six-cylinder)—Withdrew, first day.

## GOSSIP OF THE BIG SHOW.

Among the hard workers at the annual automobile shows are the advertising managers and publicity experts of the leading concerns. Probably two of the best known and, incidentally, the most industriously sought by the advertising solicitors of the Chicago daily papers, were R. H. Johnston, of the White Company, and A. N. Jervis, of the American Locomotive Motor Car Co. Both were responsible for the placing of considerable publicity, though had they accepted the pressing invitations to invest in the columns of all the dailies they would have made serious inroads into the bank accounts of their companies. There were times when various subterfuges were necessary to sidestep the persistent solicitors, some of whom always seem to be on the trail. H. T. Clinton, of the A. L. A. M. publicity bureau, was another individual whose whereabouts was the source of much concern to the advertising solicitors.

Coming of the Commercial Vehicle.—Robert D. Garden, a well-known figure in the automobile trade, in a show interview in the *Chicago Tribune*, expressed himself regarding the future of the commercial vehicle as follows: "Commercial motor cars will take the lead over pleasure cars in the future in the automobile industry. The commercial car has been neglected because the manufacturers were making plenty of money out of the pleasure car, but the future will develop a great change. The business men of the country are fast being impressed with the utility of the automobile for commercial purposes. There are hundreds of uses to which cars with capacities ranging all the way from one to five tons may be put. In Chicago the time is not far distant when all merchandise delivery and heavy trucking will be done by automobiles, and horses will practically disappear from the streets entirely."

Banquet of the Chicago Automobile Trade Association.—On Friday evening preceding the opening of the show came the banquet of the local trade association, held in the new clubhouse of the Chicago Automobile Club and attended by nearly three hundred. It was the first feast participated in by the clubmen and the dealers, the former having been in the past somewhat indifferent to the trade, though it supplied a substantial part of the membership. President Joseph F. Gunther presided as toastmaster, and the speakers included President Ira M. Cobe, of the Chicago Automobile Club; Dr. W. A. Evans, representing Mayor Busse; M. J. Foreman, Francis Simmons and Chief of Police Shippy. L. C. Boardman talked about good roads, and H. H. Gross told how to get them, while Samuel A. Miles made clear the worth of the show as an educator.

The Gathering of the Pioneers.—At the New Southern Hotel on Sunday night there was held the second annual gathering of the Pioneers, organized in 1906 for the object of uniting the "old timers" of cycling once a year. An eleventh hour notification to members was responsible for a decrease in attendance over that of the previous year, but several score partook of the frugal repast and "reminded" until nearly midnight. In the election an executive committee of five was designated, consisting of A. G. Batchelder, president; W. M. Harradon, vice-president; George G. Greenburg, secretary, treasurer; N. H. Van Sicklen, and L. C. Boardman. This quintette will do some recruiting and make the third annual a notable affair.

A few days before the opening of the show the local weather-wise man, who has a sanctum in the Auditorium tower, gave vent to an oh-be-joyful stanza. "Wait," said the wise one, "there can't be a Chicago show without snow." And so the event proved, for there were three inches of snow on Saturday; the sun retired for good on Friday, and no one has caught a glimpse of Old Sol since. Even "Joe" Ryan's seductive press work could not bring forth sunshine.

## HOW THE BAY STATE AUTOIST IS TAXED TWICE IN A YEAR

**B**OSTON, Dec. 2.—Though the automobile owners of Massachusetts have not yet recovered from their soreness at being obliged to pay a registration fee of \$5 each in the middle of the summer, the Highway Commission is getting ready to give them another prod. This will come in an announcement that on the first of January the commission will be prepared to receive from each owner of an automobile in the State the sum of \$5, which will cover registration for the year 1908. In return for the fee the commission will issue a registration certificate and also a brand new set of number plates.

The annual registration law was passed just as the legislature of 1907 was about to adjourn and it was more or less of a compromise measure between the Senate and the House. The Senate wanted a graded horsepower fee, but at the last minute gave in to the House, which desired a flat annual fee. To please the Senate the bill was permitted to go into effect on the first of August. Thus an owner who may have bought a machine in June and registered it for \$2 was required to pay \$5 more on the first of August, and will have to give up another \$5 the first of January. This process naturally met with some opposition, though the law provides that the fund that accumulates from these fees shall go towards road maintenance.

Some of the owners of cars determined not to pay the fee and they have been successful in part, for in the limited time allowed the Highway Commission was unable to secure new sets of number plates. It was therefore necessary to continue to use the old plates, and under these circumstances it has been comparatively easy for persons so inclined to escape paying the fee. The commission has issued lists of owners who did not pay and has put

these lists in the hands of the police. This measure has brought in many delayed fees, the total income from registration fees, both original and re-registration, since the new law became effective being \$63,875.

With the re-registration on the first of January, however, nobody will be able to escape payment, for the commission has devised a new number plate which is quite different from that which has been used in the last four years. The new plate has blue figures on a white background, instead of white figures on a blue background, and it also bears the numerals "1908" and the letters "Mass." After the first of the year it will be illegal to drive with one of the old plates, so it is expected that there will be a complete round-up of all the owners. The commission has bought 14,000 sets of the new plates and owners who have numbers below 14,000 can retain their old numerals by making application to the commission. Those whose numbers are over 14,000 will be given numbers which have been given up by their original holders.

It is estimated that there are now about 12,000 automobiles registered in Massachusetts. By re-registering these the commission will obtain a gross income of about \$60,000, which, added to the \$63,875 already received, will provide a fund of \$120,875. From this amount the expenses of the automobile department of the Highway Commission are to be paid, and the remainder, which should be in excess of \$100,000, will form a road maintenance fund, from which the Legislature may appropriate sums for road work. One-fourth of the fund will be for the uses of the Metropolitan Park Commission, and the other three-fourths for the Highway Commission.

### REORGANIZATION OF THE DRAGON COMPANY.

Announcement is made that the Dragon Automobile Company, of Philadelphia, has been superseded by the Dragon Motor Company, a new organization with a capitalization of \$1,000,000. The plant of the old company at Thirty-first and Chestnut streets, Philadelphia, will be taken over, and work will be carried on under entirely new lines. Special attention will be paid to the construction of taximeter cabs, 200 of which are declared to be on order, fifty of them being promised in New York City before January. The officers of the Dragon Motor Company are: J. Edward Calhoun, president; A. L. Kull, vice-president; R. G. Kelsey, secretary and treasurer. The directorate includes these officers and H. F. Rawle and C. A. Pickard, president of Salisbury Steel Works.

The factory will be handled by R. G. Kelsey, assisted by John O'Brien. John W. Haynes and J. C. Middleton will remain as assistant sales managers. It is announced that there will be at the present time very little change in the selling organization in the various cities. The A. L. Kull Automobile Company, of New York, will continue as the New York branch, while the Philadelphia and Boston branches, in charge of F. A. Broadhead and George C. Lewis, respectively, will be continued. H. P. Branstetter will remain the Dragon agent in Chicago.

In addition to the taxicab business, the regular touring car and the new roadster model will also be manufactured by the company in considerable quantities.

**East Liberty, Pa.**—The East Liberty Automobile Company, which was recently burned out, is having plans prepared for the erection of a new garage that will be much larger than the old building, in addition to being of fireproof construction. In the interim, temporary quarters are being occupied next to the ruined building.

### ALL READY FOR A GOOD SHOW AT DETROIT.

**DETROIT, MICH., Dec. 2.**—Everything is in readiness for the show of the Detroit Automobile Dealers' Association, which opens at Riverview park auditorium next Monday, continuing throughout the week. Following close on the heels of the Chicago show, many of the exhibits will be shipped direct by express from that city, thus insuring an exceptional line of cars. It is anticipated that twice as many models will be exhibited as in the past.

The suggestion was made recently that in view of the financial stringency it might be well to declare the show off, or at least postpone it until matters had straightened themselves out. A canvass of the dealers put an effectual quietus on such a move, however, they being unanimous in their determination to carry the original program through. Every foot of floor space in the spacious auditorium, which is in reality a sun garden, the entire sides and roof being glass, thus giving unexcelled light for the purpose, has been taken and dealers are vieing with each other in making their individual displays as comprehensive and attractive as possible.

### TEMPORARY RECEIVER FOR BERKSHIRE CO.

**PITTSFIELD, MASS., Dec. 3.**—Fred T. Francis, of the Berkshire Savings Bank, has been appointed by Judge John C. Crosby, of the Superior Court, temporary receiver of the Berkshire Motor Car Company, of this city. The action was taken at the instance of the company to protect creditors. Liabilities are stated at \$35,000; assets at \$30,000.

**Harmon, Pa.**—The Biarritz Auto Garage is the title of the latest addition to the garage facilities of this town. It is located at 337 Franklin street, and is owned and managed by Walter H. Biarritz. The building is modernly equipped and has a well-fitted shop for repair work.

## EARLY WINTER DOINGS OF THE AUTO CLUBS

### HARRISBURGERS ALIVE TO PRESENT DAY NEEDS.

HARRISBURG, PA., Dec. 2.—By unanimous vote of the Motor Club of Harrisburg, at an enthusiastic meeting at the Board of Trade last Friday evening, it gave a pledge to the Supervisors of Susquehanna township to bear one-half of the township's share in rebuilding as a State road the present Fort Hunter turnpike.

The question of good roads consumed the entire attention of the meeting, and general satisfaction was expressed with the rapid progress in abolishing the present toll road and starting the movement to have it replaced with a splendid macadam roadway. The club also took up the question of better roads throughout Dauphin and Cumberland counties, especially those leading into the city.

The contest committee made its report on the receipts from the automobile races held at Middletown, which showed that nearly \$750 was realized to turn over to the club treasury. The contest committee was granted permission to make arrangements for the annual endurance run next May.

The question of affiliation with the American Automobile Association was brought up, but no action will be taken until the annual meeting, when the Motor Club of Harrisburg will apply for membership at the start of the fiscal year of the Pennsylvania Motor Federation, the State organization of the A. A. A.

### SEALED BONNET CONTEST FOR CAPITAL CITY.

WASHINGTON, D. C., Nov. 30.—Promoted by a local newspaper and given under the auspices of the Automobile Club of Washington, a sealed bonnet contest will be held December 10 and the indications are it will be the best automobile event Washington automobilists have ever participated in. The route selected is rather a trying one over roads that are good in spots and exceedingly bad in some places. The distance to be covered is 114 miles, starting and finishing at the country home of the Automobile Club of Washington on the Brightwood road. The first leg will be to Olney, thence to Ridgeville, where the National pike will be taken to Frederick, Md. The contestants will then double back over the National pike to Ellicott City, and return to the starting point by way of Ashton and Burnt Mills. There are a number of stiff hills along this route, together with a thousand or more thank-you-mams, and the contestants will have their work cut out from the start.

Entries are coming in freely and the indications are there will be thirty or more cars in the contest. As this is the first event of the kind ever pulled off in the Capital City, interest in it is becoming intense and there is no doubt it will have a very stimulating effect upon automobiling here.

### BAY STATE A. A.'S INTERESTING SMOKE TALK.

BOSTON, Dec. 2.—"The Automobile Law, Its Uses and Abuses," was discussed from every conceivable standpoint at the smoke talk of the Bay State Automobile Association at the Hotel Oxford last Saturday evening. There was much of interest and value along this line brought into the full light of the day or rather night, by the speakers on the subject, and if but one-half of the suggestions advanced were adopted, both on the part of the police and the driver of a motor vehicle, there would be fewer arrests recorded.

The speakers included Chairman McClintock of the Massachusetts highway commission, President L. R. Speare, H. D. Crowell and Frank J. Tyler.

Owing to a lack of room in which to hold the smoker at the regular quarters of the club, special arrangements had been made with the hotel people so that the smoker could be held there. This followed close upon the serving of dinner in the club dining rooms, which some seventy-five members attended.

### QUAKERS PLANNING TWO-DAY NEW YEAR'S RUN.

PHILADELPHIA, Dec. 2.—The contest committee of the Quaker City Motor Club has decided on a popular innovation in arranging for its next two-days New Year endurance run. This is the conclusion of a "purely-for-pleasure" class, open to anybody and any car, and unrestricted as to schedule and checkers, except that the run must be completed within the time limit each day. And a prize cup will be awarded in the class, too, but car-performance or driver-efficiency will have nothing to do with its disposition, the cup being awarded in perpetuity to the driver in that particular class who is voted the "most popular," only those passengers, observers and drivers in the "purely-for-pleasure" class being entitled to drop a ballot. Already there are many entries from those owners who like to be "on the ground" during a contest, but who fail to extract any amusement from the strain of adhering to a schedule and observing strict rules as to bonnet-raising, adjusting, etc., under the eagle eye of an official absolver.

For those who are "out for blood" there will be three classes, with a handsome cup for each. Class A, for which the McDonald & Campbell emblem will be hung up, will be for touring cars carrying four or more; Class B, for the long, low, rakish, high-powered roadsters; and Class C, for small runabouts.

Chairman E. C. Johnson, of the Contest Committee, believes that fully 60 cars will line up for the start at 8 o'clock on New Year's day from the club's quarters at the Hotel Majestic. The first day's run will be via Willow Grove, Doylestown and Easton to Allentown, where the overnight stop will be made. The return trip will be via Hamburg, Reading, Pottstown, and Norristown—the round trip being estimated at a trifle over 200 miles.

### "LEGAL SPEED LIMIT" FOR PHILADELPHIANS.

PHILADELPHIA, Dec. 2.—The demand for another "legal speed limit" run has become so insistent that the tours and runs committee of the Automobile Club of Philadelphia is considering the advisability of promoting such an event, to be pulled off possibly on Saturday, December 14. A similar run for the Brazier Cup, about a month ago, was spoiled by a pitiless rainstorm, which not only scared off the bulk of the contestants, but marred the pleasure of those who did start. And then, as a wind-up, the officials first announced the Packard as a winner, and afterwards, on a re-inspection of the scorer's sheets, gave the run to Swain's Apperson "Jack Rabbit." Later a protest against the "Rabbit" for failure to adhere to the scheduled route coming into the city was sustained, and the cup finally awarded to the Ford, which came in second.

The run of the 14th will be open only to club members, with the same rules as obtained in Brazier Cup run as to penalties for passing the hidden checkers ahead of or behind schedule, loss of time through repairs, etc. The cup, which will be hung up by the club, will become the property of the winner.

### A. C. OF AMERICA HOLDS MONTHLY DINNER.

NEW YORK, Dec. 4.—A large number of members and guests attended the regular club dinner of the Automobile Club of America last night in the clubrooms, West Fifty-fourth street. A smoker and interesting entertainment followed the dinner. Members of the Aero Club of America, who attended the event in strong force, decided to raise a fund of \$10,000 to purchase three balloons and send a team to Germany to compete in the next race for the International Cup. Announcement is made that the Automobile Club of America will hold a ladies' day at the clubrooms on December 17, between the hours of four and six in the afternoon. Tea will be served and members are invited to bring guests. The regular monthly club dinners of the A. C. A. are proving a popular feature.

JEWEL MODEL D, SPECIAL RUNABOUT TYPE FOR 1908.

### JEWEL PRODUCES A LARGE TOURING CAR.

After graduating in the small car class, the Forest City Motor Car Company, of Massillon, O., has turned its attention to a more pretentious class of vehicle, the new model, to be known as the Jewel touring car, giving promise of being as popular in its own sphere as its smaller predecessors.

The new touring car, listed as a 40-horsepower model, has as its power plant a four-cylinder Rutenber vertical engine, with bore and stroke 4 3-4 by 5 inches, developing its normal power at 1,000 revolutions, but capable of speeding up to 1,500 revolutions per minute. Cylinders are cast separately with integral water jackets, and valves are all on one side with a single camshaft. On the 1908 model engine a new carbureter is used, made entirely of brass, this metal having proven itself to be better adapted for this work than aluminum. It is of the float feed type, compensated to give a correct mixture at all engine speeds. A double ignition system has been installed, each one entirely independent of the other. One set of spark plugs is in connection with an imported high-tension Bosch magneto, the other set with a storage battery and four-unit coil, a conveniently located switch allowing a change over from one to the other instantaneously. Engine lubrication also is of the double type, by six-feed mechanical oiler with its self-contained pump.

Standard lines of construction have been followed in the transmission, the clutch being of the leather-faced cone type, with a series of springs behind the leather, gear set of the selective sliding type, and final drive by propeller shaft to rear axle. Timken roller bearings are employed throughout in the transmission, and tow ball-bearing universal joints are provided on the propeller shaft. The rear axle is of the Timken full floating type, with the top half of the housing removable to permit of easy inspection of the bearings. Webs are cast at important points inside the housing to give additional strength. Steering gear is of the screw and nut type, spark and throttle levers being held on a quadrant above the steering wheel, but not revolving with it. Semi-elliptic

JEWEL 40-HORSEPOWER TOURING CAR—A NEWCOMER.

springs are employed in front and platform type in the rear. With a wheelbase of 117 inches there is sufficient room for a comfortable tonneau, capable of containing five people, three being on the rear seat and two on folding seats.

### BRIDGEPORT PROUD OF ITS AUTO FIRE ENGINE.

Automobiles as an aid in fighting fire have not been given the attention they deserve, probably as much from the neglect of constructors to tackle the problem of adapting a car for this purpose as from honest conservatism on the part of authorities.

At the Bridgeport factory of the Locomobile Company of America, a special machine has been brought out and has just been delivered to the Bridgeport fire department, which appears to be a highly successful attempt to adapt the automobile to fire service. Though the machine is spoken of as being adapted, it is in reality an entirely original construction, designed specially for the work it is intended to perform. A special four-cylinder 60-

BRIDGEPORT'S NEW LOCOMOBILE CHEMICAL FIRE ENGINE.

horsepower engine is mounted on a strengthened chassis with a wheelbase of 123 inches. Features of the transmission are the same as on the firm's touring cars, but adequately strengthened for the heavier work; they include selective transmission giving four speeds forward and reverse, and final drive by side chains. Total weight of the car is about 4,200 pounds, to carry which load powerful semi-elliptic springs are employed, and wheels are shod with 36 by 5-inch Fisk demountable tires.

The bodywork of the new fire fighter, built by the Bridgeport Vehicle Company, is designed to carry eight men, two on the front seats, two on each side and two on the rear, but ten in all can be accommodated if necessary. The machine is equipped with a 50-gallon Babcock chemical tank, hose reel and hose, small hand extinguishers, crowbars, axes, helmets, and other apparatus necessary for fire fighting. Warning signals are an auto chime and a bell, but as the car is capable of a speed of fifty miles an hour, and will always travel at a much faster rate than a horse-drawn engine, some third warning device may be necessary. An interesting feature of the equipment is an electrical apparatus which permits of the lighting of the big acetylene searchlight from the seat without striking a match. Painted red, with the initials B. F. D. on the radiator, the chemical fire engine presents an extremely businesslike appearance. It is now under the direct care of two attendants who received training at the Locomobile factory.

## THE AUTOMOBILE.

**CHAUFFEURS' ASSOCIATION IN QUAKER CITY.**

PHILADELPHIA, Dec. 2.—The Philadelphia Mechanical Chauffeurs' Association, an organization which first saw the light last spring, has already increased in membership to such an extent that a room was opened last week in Odd Fellows' Temple, where weekly meetings are held for the discussion of live topics and the advancement of the general interests of the association. This association now includes nearly 75 per cent. of the most proficient chauffeurs in the city, and weekly accessions are being made to the ranks. No applicant is received who cannot give evidence of his ability at his chosen occupation, and also satisfy the membership committee of his general character—morals, temperance, etc.

**A COMPARATIVE MODEL OF THE "CYCLES."**

One of the agents of the Atlas Motor Car Company, of Springfield, Mass., who modestly requests that his name be not published, has sent to the factory for inspection a clever model in wood, showing the salient points of difference between a two-cycle and four-cycle type of engine. This enthusiastic and enterprising agent of the Atlas car, the motor of which is of the two-cycle type, uses the model to clinch his argument in favor of that

UNIQUE MODELS SHOWING TWO AND FOUR-CYCLE OPERATIONS.

type of machine with his customers. The board on which the models are carved and built is hung in a convenient place in his salesroom and, as he puts it, "as soon as the customer shows the least sign of being a 'mental Missourian,' I show the prospective buyer in an unmistakable manner, that as applied to gasoline engines in particular, two solid blows on the head of a nail are more effective than four 'tenderly administered' ones."

**TRADE CHANGES IN THE QUAKER CITY.**

PHILADELPHIA, Dec. 2.—With the approach of the 1908 season comes the usual announcement of agency changes here. The most important in this connection is the addition of the American Berliet to the list represented locally by the Louis Bergdoll Motor Car Company at 323-327 North Broad street, which now handles the Imperial, Benz, and Welch. Another announcement no less important is that of the Hills Motor Car Company, 130 North Broad street, to the effect that the "full-jeweled" Corbin has been added to its line, consisting heretofore of the Royal Tourist. The Berliet had been represented here before by H. Oscar Brown, at 229 North Broad street, while the Corbin is a newcomer.

George T. Thompson, former manager of the Eastern Automobile Company, one-time representatives of the Stevens-Duryea and Lozier cars, has joined the sales force of the local branch of the Locomobile Company.

GEN. MANAGER MILES OF THE N. A. A. M. STARTS THE FRANKLIN.

**FRANKLIN ON 180-HOUR MARK-TIME RUN.**

CHICAGO, Dec. 2.—When Samuel A. Miles had cranked up the 24-horsepower Franklin air-cooled engine at Chicago last Saturday afternoon he did not climb into the drivers' seat, slip in the low and run away, for to have done so would have defeated the ends for which the Franklin people had invited him to display his skill as a chauffeur. The air-cooler has to mark time in the Chicago showroom for exactly seven days and a half, running constantly at a speed which would give thirty miles an hour if the gears were put into mesh. Next Saturday at midnight some one will throttle her down if she has not stopped before—and the Franklin people are convinced that she will not; thus a run equivalent to a trip of 5,400 miles will have been accomplished without a turn of the road wheels. With nothing more refrigerating than the warm air of the showrooms to throw upon the stationary cylinders, the demonstration is strenuous enough to prove the full worth of the waterless car.

**WHAT IS TAUGHT AT THE PACKARD SCHOOL.**

Most men, when they match their automobile, either willingly or otherwise, against a brick wall, have occasion to sigh over the length of the repair bill. Not so with the owner of a Packard, who, writing from Rochester to the factory, states: "Last night my man ran my car through a brick wall, knocking out the whole side of the barn. There was no injury to the car except smashed lamps and slightly bent mud guards. I am running the car to-day. The gentleman who performed the feat of going through a brick wall without injuring the car is a graduate of the summer class of your chauffeur's school. I presume, therefore, that the instruction in your curriculum includes detailed directions for driving a Packard through a brick wall without scratching the paint off."

WHERE THE PACKARD DELIVERED A KNOCKOUT TO THE WALL.

## BRIEF ITEMS OF NEWS AND TRADE MISCELLANY

A 4 1/2-ton Frayer-Miller gasoline truck has been purchased by Ar buckle Brothers, the big Brooklyn coffee concern.

At the American Michelin Tire Factory in Milltown, N. J., work is now carried on from 7 o'clock in the morning to midnight with a full force of skilled workmen.

The Ralph Temple Auto Company, of Chicago, has recently secured the agency for the Rapid Vehicle Company's line of commercial vehicles in that city, and has placed an order for cars for the season.

Having secured more commodious quarters at 741 Boylston street, H. C. Stratton & Company, Boston agents for the DeLuxe and Kisselkar, will shortly remove thereto from their present location on Huntington avenue.

According to telegraphic advices received by the Gearless Transmission Company, of Rochester, N. Y., a Gearless six-cylinder won the free-for-all in the hill climb at Los Angeles, Cal., on Thanksgiving Day, the time for the 34.5 miles being 6:16.

Knight & Wall, the new agents for the Dragon car at Tampa, Fla., will handle the Cuban market, and expect to make shipments of 25 Dragons to that island by January 1. The first consignment has been shipped from the Philadelphia factory.

The Milwaukee Merchants and Manufacturers' Fire and Burglar Dispatch has selected three Rambler cars for use in its service. They will be sent on emergency calls reporting fire, burglary, open safes or vaults, neglected lights, windows or unlocked doors.

Cassius F. Baker, after a trip round the country in the interests of the Pope Motor Car Company, Toledo, O., reports an increased briskness in trade. Money has been tied up, but the drift of opinion is that currency is going to be freer than ever, and that automobile business will be brisk.

As the result of a change of agency the products of the Supplementary Spiral Spring Company are now being handled in Chicago by Page & Palmer, 1712 Michigan avenue. They will have the exclusive agency for their territory, as well as for the States of Michigan and Wisconsin.

With a view to obtaining the European agency for American novelties in automobile accessories, the United Motor Industries, Limited, of London, has commissioned G. H. Smith to visit New York this month. Headquarters in the city from December 26 will be at the Hotel Astor, New York City.

After an extensive Western tour, J. D. Maxwell, designer of the Maxwell car, declares that road manners have considerably improved of late. In almost every case now automobilists will stop upon seeing the raised hand of a horse driver. On several occasions he saw automobiles help pull farm wagons over steep inclines.

The Studcbaker Brothers Manufacturing Company, South Bend, Ind., has just been notified by the Jamestown Exposition jury of awards that their exhibit of automobiles, street sprinklers, garbage and dump wagons, contractors' wagons, and trucks, has been awarded a diploma and gold medal for vehicles of that class.

The Autolyte Manufacturing Company, 26 Warren street, New York City, has

acquired the automobile department of Sibley & Pitman, at the same address. Mr. Pitman has been elected treasurer and a director in the Autolyte Company. A. H. Funke will continue as manager.

Charles A. Singer, Jr., of the Palmer & Singer Manufacturing Company, of New York, announces that he will take part in the Ormond-Daytona beach races with a Matheson car, and expresses confidence in his ability to lower the record of 50 1/5 seconds for a stock car with seven passengers, established by the late Tom Cooper in a 1906 Matheson.

Foreign appreciation of the Bosch system of ignition is shown by statistics furnished by the makers on the recent London and Paris shows. According to figures given out, 90 per cent. of the exhibiting cars at the Olympia exhibit were equipped with the Bosch magneto, and at the Paris show the proportion of complete cars with Bosch magneto was 68 per cent.

"Opponents of the six-cylinder idea," says Chas. B. Shanks, of the Winton Company, "often argue that if sixes are better than fours, then eights are better than sixes. The statement is unfair, for it is not a question of multiplicity of cylinders but of obtaining results. Eight cylinders, or any other number beyond six, cannot do more than the six in producing continuous power."

The Acme Sextuplet, the new six-cylinder product of the Acme Motor Car Company, of Reading, Pa., is having an excellent sale, according to reports from W. J. Flinn, traveling sales manager for the company. Shipments have been made to San Francisco, Los Angeles, Boston, and Chicago, and Mr. Flinn is to receive this week in New York City the first of the six-cylinder Acme runabouts, with which he will give practical demonstrations in the Eastern States.

Every owner of a Rambler automobile who can furnish proof of having driven his car 15,000 miles is eligible for membership in the Rambler Fifteen Thousand Club. The president of this body must have qualified for membership with the least expenditure for fuel, oil and repairs; the vice-president will be the owner of the oldest Rambler car still in daily service. The second vice-presidency will go to the owner who has actually covered the greatest distance; the secretary must have accomplished the most successful and economical single trip of greatest length, and the treasurer will be the conservative and sane driver who has never been fined for speeding. Rambler owners have caught the spirit of the movement and hundreds of applications are being sent to Thomas B. Jeffery & Company, Kenosha, Wis., for membership.

### NEW AGENCIES ESTABLISHED.

The Corbin Motor Vehicle Corporation, of New Britain, Conn., has closed its branch house in the Motor Mart at Boston and placed the local agency with George J. Dunham, at 182 Columbus avenue, who will also handle the Royal Tourist.

Recent agencies appointed for the Corbin Motor Vehicle Corporation include the following: Reese Motor Car Company, Cleveland; Covey & Wallace Motor Company, Portland, Ore.; Pacific Coast Automobile Company, Seattle, Wash.; Inland Auto

Company, Walla Walla, Wash.; B. S. Bernard, Troy, N. Y.; Carlton Garage & Repair Company, Brooklyn, N. Y.; Clark & Davis, Syracuse, N. Y.; Wirick-Bennett Auto Company, Sioux City, Ia.; Bell Bros., Stamford, Conn.; Bridgeport Auto Company, Bridgeport, Conn.; New Haven Auto Corporation, New Haven, Conn.; E. H. Towle Company, Waterbury, Conn.; Pyramid Motor Car Company, Danbury, Conn.

### PERSONAL TRADE MENTION.

W. W. Burke has resigned as manager of the Motor Parts Company, 25 West Forty-second street, New York City, with future plans not yet announced.

Emil Grossman, president of the National Sales Corporation, of New York City, starts this week for a five or six weeks' business trip through the middle west and far west.

F. C. Lindoerfer, who for the past three months has been associated with the sales department of the Logan Construction Company, Chillicothe, O., has severed all connection with that concern.

Charles A. Davis, formerly with the G & J Tire Company, as Pacific Coast manager, has joined the selling force of the Michelin Tire Company. Mr. Davis will be the special factory representative to the Pacific Coast trade.

E. R. Benson, formerly secretary of the Hartford Rubber Works Company, Hartford, Conn., and head of the sales department, has resigned to accept an important place in the sales department of the Cadillac Motor Car Company, Detroit, Mich.

Oscar Stevenson, of New York City, secretary of the York Motor Car Company, York, Pa., has joined the office staff at the latter city, and will remain for some time to supervise the 1908 output at the home of the Pullman automobile. H. R. Averill, sales manager of the company, is attending the Chicago show during the present week.

C. S. Johnston, treasurer and general manager of the Continental Auto Manufacturing Company, New Haven, Conn., has sold out his entire holdings in that concern, and in future will only be connected with the Continental car in helping to increase its sales when it does not conflict with any other interest that he may take up in the automobile industry.

D. W. Henry, for the past five years a general representative of the Electric Vehicle Company, Hartford, Conn., has just assumed charge of all the agencies of the Columbus Buggy Company, Columbus, O. This company will devote considerable attention to turning out its air-cooled high-wheeler in quantities during the coming season, in addition to its quota of electric, which will also be increased.

Roy F. York, vice-president and sales manager of the F. B. Stearns Company, has left for the Pacific coast and will visit the numerous new Stearns agencies established throughout the West. Mr. York regards the great west as one of the coming big fields for the sale of high-powered automobiles of the better class. "Our company for some years past has felt a strong and growing demand for cars from the western part of the United States," he said, "and each year a large share of our output is shipped

to western dealers. One result of the success with which Stearns machines have met is the opening of many new agencies throughout the West." All of these will be visited by Mr. York on his trip.

**A NEW THOMAS MANAGER.**

A valuable addition to the forces of the E. R. Thomas Motor Company, Buffalo, N. Y., has been made in the person of E. C. Morse, recently appointed to take charge

E. C. MORSE.

of the sales department, advertising and commercial end of the business. Mr. Morse comes to the automobile industry with a good reputation as commercial manager with the National Cash Register Company, at Buffalo.

**FORD COMMERCIAL MANAGER.**

Rapid growth of business has compelled James Couzens, of the Ford Motor Company, to relieve himself of some of the burden connected with the management of the sales department of his concern, and N. A. Hawkins has been appointed to the position of commercial manager, Mr. Couzens being left free to look after general affairs.

N. A. HAWKINS.

Though new to the automobile public, Mr. Hawkins is no stranger to the Ford interest, having in his capacity of auditor and adviser, been closely connected with Messrs. Ford and Couzens since the inception of the company. He is thoroughly familiar with every department of the concern, acquainted with every member of the organization, and will be an invaluable addition to Ford forces by reason of his exceptional ability in organizing and systematizing.

**NEW TRADE PUBLICATIONS.**

From the Niles-Bement-Pond Company, of New York, comes a well produced illustrated catalogue dealing with the firm's 21-inch and 28-inch rigid turret lathes. Illustrations are given of the lathe on various classes of work, and

examples given of various classes of work which can be done.

A six-page folder has been published by the Apperson Bros. Automobile Company, of Kokomo, Ind., calling attention to the fact that out of a total of 73 of the most prominent automobile owners in one of our large cities, as per list selected by a well-known and conservative newspaper, over 40 per cent. had purchased Appersons.

A handsome illustrated pamphlet has just been produced by the Continental Caoutchouc Company, descriptive of the demountable rim introduced by that concern. The invention, which has been named the Continental Ready Flated tire, allows of the carrying of an inflated tire on a separate rim ready to be fixed on the wheel with the delay of but a few minutes whenever a puncture makes a change necessary.

An interesting publication dealing with vanadium steel for use in automobile construction has been sent out by G. F. Ehrenzeller, Pennsylvania Building, Philadelphia, sole agent in the United States and Canada for Willans & Robinson, Limited, of Queen's Ferry, Flints. A valuable comparative table is given, showing average static and dynamic tests of the various steels manufactured at the Queen's Ferry works. The publication will be useful to automobile manufacturers, from the fact that it deals exclusively with steels for automobile work, specific examples being given of crankshafts and axles, springs, forgings and stampings of all sorts, hollow shafts, tubes for frame work, gear wheel blanks and all classes of forgings.

There is much more than mere platitudes in the 60-page instruction book just issued by the Ford Motor Company, Detroit, Mich. The work has been produced to assist owners of 1906 and 1907 Ford models in a complete understanding and care of their cars, and is certainly one of the most complete and valuable publications of its kind ever sent out by a manufacturer. It contains a photographic reproduction of every part, bolt, nut and screw on the 1906 and 1907 models, with complete instructions for the adjustment, removal and replacement of each, the cost of photographing, retouching, cuts and printing alone amounting to about \$5,000. As an example of how thoroughly the work is done, for the motor alone there are 98 distinct illustrations, each one numbered and named, and its price indicated. The book is not intended for general publication, but an endeavor is made to obtain the name of every Ford owner and send one to him direct. It is naturally difficult to trace all owners, on account of cars changing hands and other reasons, but a copy will be sent to every person possessing a Ford immediately on receipt of name and address.

**INFORMATION FOR AUTO USERS.**

**Improved Storage Batteries.**—Several new and improved features have been incorporated in the storage batteries produced at the Schug Electric Manufacturing Company's factory in Detroit, Mich. As a protection against breakage, the Schug battery is built with separate rubber jars and protected with an outer case of wood. Instead of using screws and nails to hold the case together, as is often done, maple pins are employed; there is thus nothing to corrode and no danger whatever of the bottom of the case falling out. The cells are joined together with burned-in lead connectors, the terminals being brought over the side of the box.

The only metal parts not made of lead are the screws and washers used to fasten the rubber handle or strap to the box, and the brass thumb screw for fastening the wires to the battery. The top of the

THE SCHUG STORAGE BATTERY.

battery is sealed over with a special acid-proof compound. The improved construction increases cost a little, but this is more than regained by the longer life of the batteries. Three sizes are made, 40, 60 and 80 amperes, all 6 volts.

**Bullard Speedometer Bracket.**—A chain being no stronger than its weakest link, speed indicators have often been considerably diminished in value by the weakness and unsuitability of the method of attaching the cable to the road wheel. What is claimed to be an improvement on any device yet put on the market has been produced by J. H. Bullard, manufacturer of automobile specialties, of Springfield, Mass. The accompanying illustration shows the general design of the Bullard improvement, consisting of a gear

DETAIL OF THE BULLARD BRACKET.

bracket and connections by means of which the speedometer shaft can be connected to the arm of the steering knuckle by the use of only three screws. It is declared that no American machine has yet been found that one of these connections will not fit. Fig. 1 shows the bracket and gear box complete with the driven gear, AA being the two bolts that hold the clamps B on the small end of the ball-standard and also clamp the neck of the gear box, allowing it to be turned at any angle. The standard C is made of the best quality of soft steel and can be bent between the balls at a right angle if necessary, so as to fit where a straight standard could not be used.

# THE AUTOMOBILE

## PUBLISHERS' SPECIAL ANNOUNCEMENT TO ALL SUBSCRIBERS

### NEW SUBSCRIPTION RATE

Owing to extensive improvements in **THE AUTOMOBILE**, as well as to general increased cost of production, the subscription rates will be

**\$3.00 A YEAR**

after January 1, 1908, and all amounts mailed after that date will be credited at that rate.

All present subscribers and subscriptions mailed before January 1, 1908, may renew for any period from the date of any expiration as shown on the wrapper at the present rate of

**\$2.00 A YEAR**

All subscriptions renewed for 5 years for \$10, now paid to some period of 1908 will be credited to January 1, 1914, or all subscriptions expiring this year (1907) may renew to January 1, 1914, by paying \$11 before January 1, 1908.

### REASON WHY

When the \$2 a year price was established in 1902 **THE AUTOMOBILE** gave its readers 22 editorial pages, with 15 to 20 illustrations.

This year **THE AUTOMOBILE** gives its readers an average of 40 editorial pages, with 50 to 60 illustrations, at an editorial expense of production per issue of three times the cost of the issues when the price of \$2 was made.

**THE AUTOMOBILE** is ably, conscientiously and efficiently edited. It has a complete staff for both its news and engineering features, and its policy is to reflect in all its phases the great and growing industry for which it speaks.

During these years **THE AUTOMOBILE** has sold and is selling to legitimate readers many more copies than any other publication in the field.

### RENEW AT ONCE

while the matter is before you, avoiding the increased rate for any period covered by your renewal. Improvements in the paper will continue. Time is valuable. You cannot afford to read cheap papers.

No. 24

## WHAT SAVANNAH OFFERS FOR A ROAD COURSE

SAVANNAH, GA., Dec. 9.—The Savannah Automobile Club is thoroughly in earnest in its efforts to have the availability and desirability of this city made known as the proper place for the holding of one of the big automobile road races. President F. C. Battey and his associates intend to leave no stone unturned to bring about the holding of an automobile event some time during the winter. According to information printed in the Savannah papers and given out by members of the club, the aid of the American Automobile Association has been solicited in the undertaking. The Mayor and other city officials and prominent citizens are greatly interested in the project, and it would appear that the Savannah club will be successful in its efforts to bring about a big road race.

In the near future the club will effect the organization of the Georgia State Automobile Association of the national body, and it is not improbable that should any profits accrue from the race intended to be held, it will be divided between the local club and the State body and used for the general good of all autoists.

Ten miles of almost perfect road are available for the course, the disposition being an east and west stretch, each four miles long and almost straight, joined by a north and a south road, each a mile in length. The starting and finishing point would be at the north end of the course, at Dale road or Forty-second street, just on the limits of the city of Savannah. At no point is the course crossed by other roads, and the only traffic intersecting it is a car line, the management of which has agreed to suspend operations during the meet. Road surface throughout is excellent macadam, the soil being of such a nature that even heavy rains only affect it for a few hours. The country being exceptionally level, and the roads unusually straight, the fastest speed would be possible with safety.

The climate of the district is one of the most equable in the country, the weather in January being usually very good, so that there would be little danger of rain interfering with the meet. From the viewpoint of picturesqueness, the course has few equals, the beautiful overhanging foliage forming a charm-

ALONG THE VERNON ROAD THERE IS A MOST PICTURESQUE CANOPY OF ANCIENT LIVE OAKS AND DROOPING SPANISH MOSS.

Photographs by M. Edward Wilson, Savannah, Ga.

CAUSEWAY ON LA ROCHE AVENUE, A MODEL ROAD SURFACE.

ing setting. Probably the only objection which could be brought against the course is its shortness. From the spectators' standpoint, however, ten miles is an advantage, for it will give frequent passage of the racers; policing and guarding of the course would, in addition, be simplified by the short length.

While the ten-mile course is preferred by the local automobilists, should there be a positive demand for a larger circuit, it is possible to arrange for one of twenty-two miles, taking in a couple of roads which are not quite up to the standard, but would be plenty good enough for road racing and perhaps would add to the strenuousness of the event.

Savannah is easily accessible by some of the finest steamships sailing from Baltimore, Philadelphia, Boston and New York.

#### Savannah Editor Invites the Autoists.

Referring editorially to the project, the *Savannah News* expresses itself in the following terms:

"Bringing the big automobile meet in January to this city will be a good thing for all parties concerned, and we feel confident that it will be the beginning of regular annual meets of the same character here. No section of the country available for winter racing, not excepting California, offers so many advantages as do Savannah and Chatham County. The roads hereabouts are exceptionally fine and almost level, and the character of the soil is such that even heavy rains do not affect them for more than a few hours; and even in the heaviest rains the roads never become impracticable. In January, however, the weather is usually good, so that there is practically no danger of rains interfering with the races. Our climate is the most equable on the continent, so that extremes of weather need not be taken into consideration. When the visiting and competing automobilists have come and seen and driven over our roads, they cannot be otherwise than delighted, and when they go home they will advertise us to their friends, and those friends will wish to come and experience the pleasure themselves. Every effort should be put forward to the end of making this first big meet in Savannah a success in every way."

THUNDERBOLT ROAD HAS A GOOD START AND FINISH PLACE.

ON THE WATERS ROAD IS GREATEST 'HILL' ON ENTIRE ROUTE.

#### GRAND PRIX MANAGER VISITING AMERICA.

Among the passengers on board the storm-delayed *Touraine* which warped into the French line pier on Monday morning last was Victor Breyer, president of the Board of Management of the Velodrome Buffalo, Paris. Mr. Breyer, who is on a short visit to the United States, is best known to the public on this side of the Atlantic as the manager of the French Grand Prix of the Automobile Club of France, run on the Dieppe circuit last July, and the first road race in France which had been made a financial success. The organization of the race was, in the opinion of all experts, the most perfect the world has ever seen, this excellent result being in great measure due to the efforts of the manager.

#### A. A. A. BOARD PLANS STOCK CHASSIS RACE.

At the first meeting of the new Technical Board of the A. A. A., with Chairman N. H. Van Sicklen presiding, held in Chicago, December 6, a committee was designated to draft rules for a national stock chassis race which will probably take place early in June, somewhere in the Middle West. A. L. Riker, Edgar Apperson, Henry Souther, E. R. Thomas, and Henry Ford were named. A. C. Newby, Edgar Apperson, and H. O. Smith, all from Indiana, will investigate and find out whether an Indiana course is available.

#### THE POWER BOAT SHOW IN THE PALACE.

Though they were not all weather beaten sea dogs who entered the Grand Central Palace, on Lexington avenue, New York City, last Saturday night, there was a distinctly nautical air about the building recently occupied by automobiles and now given up for seven days to the manufacturers of power boats.

ISLE OF HOPE ROAD IS ANOTHER TROPICAL STRETCH.

## ACTIVE AUTO DOINGS OUT ON THE PACIFIC COAST

SAN FRANCISCO, Dec. 3.—A battle royal threatens to disturb the quiet of "Automobile Row." Once more the question of holding a show in San Francisco this season is being agitated. Several months ago it was definitely decided to hold the event, the date was set, and it was the aim of all the members of the Dealers' Association of California to make the exhibition, to be held from the ninth to the fifteenth of December, one to be proud of, greatly surpassing, in every way, the one of last year. Committees were appointed, the place was chosen for the display of the new models, and extensive preparations were being made, when the conditions of the money market caused some of them to pause and consider. Things looked a little grave, and at one of the meetings, after much discussion, pro and con, the show was called off for the season. This was, however, not unanimous, many of the dealers wishing to exhibit their new cars in a competitive atmosphere, and as the outcome another meeting was held behind closed doors.

Most of the cars are consigned, or sent to the coast, removable from the freight cars only upon the payment of the draft accompanying the bill of lading. The unsettled financial state of the banks made it seem to the dealers impossible to raise the sum of money required to release these show cars. Those who found themselves in this position were, consequently, opposed to accruing indebtedness by holding the exhibition. The result of the meeting was the same as the former one. Fred J. Linz, manager of the Maxwell-Briscoe Company of the Pacific, and vice-president of the Dealers' Association, was absent from the city on a business trip to Oregon and Washington when both meetings were held and decisions were made against the show question. Mr. Linz heard of this in the North, and did not even wait to reach home, but wrote several letters promoting an exhibit. Upon his return he interviewed many of the dealers and found that the forces were almost evenly divided. So the battle is on, for those who desire to exhibit publicly must obtain a sanction from the Dealers' Association. The result is hard to foresee, but there is little doubt but that an event in the nature of a salon will take place some time in February.

### Riverside's Annual Hill Climb a Success.

LOS ANGELES, CAL., Dec. 1.—Hill climbs, runs, races and contests always have their surprises and disappointments. This was no exception, but the surprises came mostly with the disappointments. Cars which were expected to show wonders failed to perform, but, as freely predicted, the former record of 5:41 2-5, held by a six-cylinder Stearns, was lowered a fraction less than twenty seconds by a Stoddard-Dayton, driven by Frank Seifert. In the \$2,500 runabout class this car made the four miles in 5:21 1-2. A little bunch of nerves, Paul Derkum, went on a motorcycle up the long hill in 4:21. This is the fastest time ever known over the course, being close to a mile a minute speed for a rise of 700 feet in four miles.

The best time of the day for touring cars was made by a two-cylinder Tourist, driven by George Kussman. The climb was made in 5:42 1-2 in the class for cars costing \$2,000 and under.

In the class for runabouts costing \$3,000 and less, there was but one entry, the Stoddard-Dayton. The climb was in the nature of a warm up, and, after coming up in 5:31 1-2, the car was hurried down the hill to meet the new Haynes roadster in the free-for-all runabout class. The Stoddard-Dayton after its warming-up heat was even better and rolled the distance in 5:23. Frank Seifert drove as fast as the machine would go, and in the third time up, the \$2,500 class, made his record of 5:21 1-2.

The two-cylinder Tourist and the smaller Oldsmobile were the sole starters in the class for touring cars costing \$2,000 and under, and the Tourist was an easy winner in 5:42 1-2.

In the touring car class, \$3,000 and under, P. A. Renton, with the Great Smith, won the cup for the class, his time being 6:43 1-2. Scratches cut the free-for-all touring car class down to four starters, and two of these, the Stearns and the Thomas Detroit, failed to finish. The Gearless went up in 6:17 and the White steamer in 6:27. D. M. Lee's Cadillac proved a winner in the \$2,500 touring car class. The day's sport closed with the \$4,000 touring car class for the Glenwood Inn Cup, a handsome copper masterpiece of the jeweler's art. It was won by an American in 5:56 2-5.

### White Steamers Tie in the Del Monte Endurance Run.

There were four contestants in the recent event for the Del Monte endurance run cup, given by the Automobile Club of California. The White Company was represented by two cars, one driven by J. J. Borree and the other by Al. Piepenberg, and opposed to the steamers were two Tourist cars, one driven by

WHITE STEAMER, WHICH TIED FOR THE DEL MONTE CUP. 127

J. A. Nickrent and the other by E. E. Mason. Friday morning, November 22, at 7 o'clock, the signal was given at Belvedere by Chairman A. B. Watson of the club, and the four cars were sent away at fifteen-minute intervals. The course from Belvedere to Witter was covered by all four cars on schedule time. Then the quartette remained at Witter for the return trip on the following Monday.

In addition to the Del Monte cup was another contest for the Witter trophy, which was won by E. L. Peacock, driving a Mitchell. J. H. Berup, driving a contesting Lambert, protested the award of the Witter trophy, claiming that he had been unable to pass his opponent on account of the narrow road.

The Witter hill climbing contest took place on Saturday afternoon, the course being two miles long and containing many sharp curves and turns. A Buick won the challenge cup in 6:21, and was also successful in the free-for-all.

Monday morning the quartette of strivers for the Del Monte cup again resumed their struggle. Ten miles out of Middletown the Tourist had a narrow escape from going over the edge of an embankment and was rescued from the perilous position by one of the White steamers. The conclusion of the run resulted in a tie between the two White steamers.

## BRITAIN WILL COMPETE CONTINENTALLY AND AT HOME

By JOSEPH F. MACKLE.

LONDON, Dec. 3.—Since the death of the Gordon Bennett contest the British attitude towards Continental races has been one of indifference, and, with the exception of the two unlucky eight-cylinder Weigels, no British car has shown its paces in French or Italian contests during the past two years. Maturc consideration would seem to show that this has not been altogether the wisest of policies. The popularity of the big European races has suffered not one whit from the absence of British participants and without doubt much business has accrued to the winners of these races from British buyers.

The coming season will see a reversal of this stand-off policy. Many of the leading makers have announced their intention of competing for the Grand Prix race, and both the Ariel and the Deasy concerns have their cars on the road already. Napier will build special cars to suit the conditions of every European race of note, and S. F. Edge is confident of adding to the big speed reputation which Napier's have lately won at Brooklands and Gaillon. From other firms, as well, come indications of renewed activity for the racing game, and quite possibly the French will find Britain following in the steps of the Italians and wresting their laurels from them during the coming season.

### Conditions for Tourist Trophy Event.

For events at home the new season's plans are already cut and dried. The Tourist Trophy race, has served its purpose. It demonstrated the big speed possibilities of the moderate-powered light car, and at the same time brought about big improvements in petrol economy—improvements which show to advantage in the stock models of competing firms. Hardly anything was to be gained by the continuance of this race, and so, like the Gordon Bennett of good memory, it has given place to a new contest. This is to have no fuel limit, but will be a race pure and simple, open to cars of four or more cylinders, whose D·N dimensions (D being the diameter of the cylinders in inches and N

the number of cylinders) do not exceed 64. For four-cylinder engines, this gives a maximum bore of four inches, whence the event is popularly styled the "four-inch" race. The minimum weight will be 1,800 pounds, exclusive of driver, mechanic, tools, and spares. The distance proposed is about 350 miles, and the race will take place in the Isle of Man about next May.

### Reliability Run Considers Time Alone.

The reliability trial side of the program has been looked after by the Society of Motor Manufacturers and Traders, and rules have been drawn up for an event bearing the imposing title of "The International Motor Contest, United Kingdom, 1908." The contest is to consist of a 2,000-mile observed reliability run in daily stages of about 200 miles, the tour starting and finishing at London. On the journey there will be some 20 miles of timed hill-climbs, and at the end a 200-mile speed race will be held at Brooklands.

A novel and good point about this event will be the absence of arbitrary or complicated methods of judging. The record will be by time alone, that is, time taken to climb the hills and at Brooklands, time spent in adjustments and repairs, and time lost in filling petrol tanks, this last being counted at one minute for each gallon. The cars will be started for the final 200-mile race in each class according to their respective time records at their arrival at Brooklands. Therefore, the first car past the post in each class will be the winner.

No attention has been paid to such qualities as silence, springing or absence of vibration, the committee responsible for the rules rightly agreeing that such points as these can easily be judged by a potential purchaser in the course of a trial run, leaving the more important points, which cannot be so readily judged, to be settled by the big contest. This general proposal has met with much approval, and in all probability the event will be well supported by the trade.

## AN AMERICAN BROOKLANDS TO BE NEAR PHILADELPHIA?

PHILADELPHIA, Dec. 9.—In the multiplicity of projects now going the rounds for the establishment of an American Brooklands in the East, the average automobilist is apt to take the announcement of a new one *cum grano salis*. But the scheme outlined for the American Autodrome, to be laid down within 15 minutes' drive of the Philadelphia City Hall, bears all the earmarks of being a go, backed as it is by some of the Quaker City's most prominent business men, with practically unlimited capital behind them.

The new track, which is to be a two-mile concrete and cinder oval, 100 feet wide, except on the turns, where it will be 125 feet, will be built at Llanerch, on the West Chester pike, about two miles west of the Sixty-ninth street terminal of the Market street elevated road. With the schedule now in force Llanerch is about 25 minutes from City Hall by trolley. On race days expresses can do the distance in 20 minutes or less.

The motordrome scheme is an idea of W. F. Magraw, a

prominent real estate man, who succeeded in interesting Louis Bergdoll, the millionaire brewer and automobilist, in the project. The ground upon which the track will be built lies high and can be banked and graded at comparatively small expense. There are about 225 acres in the plot, and the engineers who are now at work staking the oval will arrange for several entrances from the surrounding roads, under the track, and into the infield. In many other respects the ideas incorporated into the Brooklands track will be followed, Mr. Magraw having made a special trip to England to study the details of that record-breaker. An expenditure of half a million dollars will be required to complete the track and all its appurtenances, but just at present all the promoters' energies will be devoted to building the track and entrances, which will be completed before July 4, if present plans do not go awry. In connection with the track it is proposed to form an automobile club, which shall eventually take over the entire plant.

Berlin now possesses a certificated woman aeronaut in the person of Frau la Quiante, an officer's wife, who has successfully passed her examination in both the theoretical and practical branches.

As the German Emperor's travels have upset all previous arrangements, he will not be able to open the Berlin show on December 5. The Crown Prince will assume this duty, as he did last year, and both he and Prince Henry of Prussia have promised to attend the banquet at night.

At the Paris congress the dates for the 2,400-kilometer Prince Henry tour were fixed for June 9 to 17, while the Kiel Week takes place from June 22 to 29.

A motordrome on the Brooklands idea is being proposed for Berlin, the site to be probably at Tetlow.

Austria's motor regulations have been unpleasantly enhanced by a decree of the Home Office, fixing the highest speed permissible on the open road at 30 kilometers. Until now this limit referred only to towns and villages.

# WHAT TWO AMERICANS FOUND AT THE SALON

BY ALFRED REEVES, GENERAL MANAGER AMERICAN MOTOR CAR MANUFACTURERS' ASSOCIATION.

PARIS, Dec. 1.—After all is said and done in the matter of automobile shows, the present exhibition in the Grand Palais, which closed to-night, must be considered the last word. Because of a mammoth and beautiful building, built originally for the Paris Exhibition, it is possible here to house an exhibition of automobiles which is without doubt the finest industrial show ever held anywhere. To Americans the show is nothing short of dazzling, even though they are trained to some pretty good affairs at home. In company with Howard C. Marmon, of Indianapolis, who is a member of the Technical Committee of the A. M. C. M. A., I spent almost a week over the exhibits, finding new and interesting things at every turn.

HOWARD C. MARMON,  
Technical Committee A.M.C.M.A.

No word artist can attempt to paint the decorative and electrical features that surround the finest productions of the motor car industry of France, Italy, Germany, Belgium, Holland, Switzerland, Spain, England and America. Under the glass roof of the wonderful Grand Palais, a building probably six times as large as Madison Square Garden or Grand Central Palace, are shown the glittering automobiles of the world's greatest factories. Thousands of variegated colored incandescent lamps, outside and inside the building, set off by two score of

giant searchlights (the whole lighting system costing \$600 an hour for current alone), produced a veritable fairyland setting that dazzled and astonished even the artistic Frenchmen, to say nothing of its effect on Americans visiting the show for the first time.

Imagine a great hall almost 1,000 feet long and about 500 feet wide, with a dome of solid massed electric lights; imagine four solid supporting columns of fire, of the most graceful lines, rising to the centerpiece, showing a sunburst that seemed striving to overcome the glow of sixteen searchlights, the whole being surrounded with gold and white draperies of light; imagine a sky of shimmering silver cloth, accentuated by a score of flashing searchlights, with side decorations of glowing club shields and borders of fleurs-de-lys.

Imagine a floor almost a quarter-mile square carrying hundreds of polished cars and decorated with electric signs of an infinite variety ranging from reproductions of fruits, flags, flowers, and arches in lights of every known color and form to the gigantic Darracq illuminated globe in the center; imagine the aisles and booths crowded with bejeweled women whose gems vied with the electric lights that flashed back defiance, and with silk-hatted men as escorts. Then imagine outside the building half a dozen boulevards

ALFRED REEVES,  
Gen. Manager of the A.M.C.M.A.

SCENE OUTSIDE THE GRAND PALAIS DURING THE HEIGHT OF THE GREAT EXHIBITION PRESENTED BY THE FRENCH INDUSTRY.

wards leading to the Palais being strung with thousands of electric lights in flower form, attached to majestic columns or hidden among sculpture work. Add to this a dozen or more electrically colored fountains, a horde of slow-moving autos with honking horns and staccato-like exhaust taking people to and from the show. Above, the majestic Eiffel tower casting a searchlight over all and a dozen revolving lights in front of the building. Finally, imagine the tale of the Arabian Nights or of a Roman spectacle, and you will have a faint idea of the brilliancy, richness, and perfection of what is unquestionably the world's greatest automobile show.

#### The Greatest of Automobile Shows.

Every effort was made to have this the greatest of all shows, and the efforts proved successful. From the band of 100 pieces to the very smallest detail, the public was impressed with the importance of the automobile, particularly with the position of France in the industry, and the public has shown its appreciation by attending in record numbers, there being 60,000 paid admissions last Sunday, with an average attendance each day of about 30,000. While there is some talk among the few of making this the last show because of the expense, which is very much greater than falls on exhibitors at American shows, yet it is admitted that shows can profitably be held for two or three years more, especially if a uniform style of decoration is followed out that will decrease the cost of individual exhibitors, some of whom at this show expended between \$8,000 and \$9,000.

While, of course, the exhibitors from France were in the great majority, there was an excellent representation from other countries, including an exhibit of the Ford Motor Company, the only one from America. The Ford made a big hit at the show, the stand being constantly surrounded by visitors, and many retail sales being made, besides arranging for agencies. Mr. Lockwood, who represented the Ford Company, says that with the exception of Turkey, where all motor cars have been barred, Ford machines are now used in every civilized country.

It was rather a novel thing here to see the show close at 7 o'clock in the evening. It opened at about 9 o'clock in the morning, but from 12 to 2 the building was practically deserted, as every good Frenchman takes at least two hours for *dejeuner* as against the American custom, where a light meal is considered the proper thing at midday. Great crowds attended in the afternoon, with the select element arriving at about 5 o'clock and remaining until the close. The admission was only a franc, but there were several days when it was 5 francs.

While there are no very radical changes in construction, there are many improvements in minor details that make for the perfect car. Generally speaking, prices have been reduced anywhere from 10 to 20 per cent, and special reductions are being made where cars are being sent to America, so that in many cases complete French cars of good reputation will be sold in 1908 on a price level with some of our best makes.

As might be expected, the business this year has been in small cars, and almost every maker exhibited cars of from 10 to 20 horsepower. Some of these have one cylinder in the case of runabouts; others two, but most of them four. The trade in big cars this year has not been good. The tendency of the makers and dealers is to be a little conservative next year. Prices of the small cars do not compare with ours, and there seems a fair field over here for cars for the masses.

#### Some of Mr. Marmon's Technical Impressions.

In my judgment, Howard C. Marmon, my associate on this trip, is one of the closest students of motor car construction that we have, and his opinions as obtained from a review of the show, are well worth considering. Of course, to our A. M. C. M. A. members will be given an exhaustive report of our investigations in Europe, but certain points are worth noting publicly for the benefit of the trade as a whole. In conversation regarding the impressions of an American engineer at the Paris show, Mr. Marmon said:

"The present exhibition discloses the general feeling of dissatisfaction among designers as to detail points that had come to be regarded as conventional, and the details in the cars show here every possible variation that well or ill directed ingenuity can suggest.

"Motor designs in general show a tendency to increase the number of cylinders in one casting. Small four-cylinder motors of from 10 to 18 horsepower are cast *en bloc*. Six-cylinder motors are usually in two sets of three cylinders.

"The greatest possible diversity is shown in mounting motors. The crankcases may have four separate arms cast on each side and carried out to the main frame, or may be made without arms and bolted directly to pressed steel or cast cross frame members or a very narrow sub-frame running parallel with the crankshaft. They are mounted with two crankcase arms near the flywheel, and a single point in front, or vice versa. This list only indicates some of the more common methods. Not many ball-bearing motors are shown. The circulating oil system of flood lubrication has been largely adopted.

"High-tension magneto ignition is gaining ground, as some of the most prominent advocates of make-and-break show either part or all their models fitted with a high-tension magneto.

"In heavy cars a number of examples of electric transmission are shown. The dynamo and motor may be mounted in the frame and used as an ordinary change-speed device, or the motors may be placed either in the front wheels or in the rear wheel hubs. Among the small cars of the two-passenger variety—of which many new varieties are shown—there are disk friction drives, flat belt drives, and V-belt drives on expansible pulleys, in addition to slip and planetary gear transmission. The small runabout is usually a one-cylinder vertical.

#### Some Self-starting Devices in Evidence.

"The most largely used starting device consists of a compressed air tank, a small air compressor driven either off the camshaft or the layshaft of the transmission, and a gear-driven air distributor to admit air to the cylinders in rotation at the top of their compression stroke through a check valve. As soon as the compressed air is turning the motor over at the necessary speed, it automatically takes up its normal functions and the air valve is closed by hand.

"The most noticeable innovation in rear-axle construction is the placing of the differential gear on the propeller shaft and driving through two sets of beveled wheels. When this is done the rear wheels are cambered.

"Great variety is shown in springing the rear end of the chassis frame. Semi-elliptic, three-quarter elliptic, full elliptic with solid ends, full elliptic with scroll ends, platform springs, a modified form of full-elliptic in which the upper half is one-half the length of the lower half, spiral springs, reach springs, and "C" springs are among those on view. The three-quarter elliptic is mostly used. Complete town cars are shown in which the inclosed part of the body is mounted on four "C" springs and swung by them above the chassis frame.

"Two extremes of practice are shown in frame construction. Some makers choose to adopt very light and flexible frames, while other makers, in an effort to get extreme rigidity, carry the sides of the pressed steel frames up sufficiently high to form the lower half of the body. Straight line bodies are very rare. The closed body is slightly convex, and the open body either slightly convex or a restrained King of Belgians type.

Although well used to seeing streets full of automobiles in New York and elsewhere, one cannot fail to be impressed with the standing of automobiles in Paris. It is simply full of them, and honking horns are heard every hour of the day and many hours of the night. Your Frenchman uses his car a great deal in business, and everybody else uses the taxicabs or the horse-drawn cabs, for other than these for transportation there are only a couple of steam trams and an underground system of rather limited capacity. Taxicabs have been in evidence for about two years and there are now about 3,000 in circulation.

**E. V. COMPANY PLACED IN RECEIVERS' HANDS.**

Inability, either to borrow or to collect what was due it, owing to the present stringent conditions, is given as the cause of the failure of the Electric Vehicle Company, Hartford, Conn., for which Halsey M. Barrett, of Newark, N. J., and Henry W. Nuckles, an officer of the company, were appointed receivers for the State of New Jersey by Judge Cross, of the United States Circuit Court in Newark, on Tuesday last. William S. Montgomery was also appointed at the same time by Judge Ward, of the United States Circuit Court in New York City, to serve with Mr. Barrett as ancillary receivers for the State of New York. It had been reported that the company was in financial straits recently, and action was precipitated by its default of payment of an issue of \$2,500,000 of 6 per cent. gold bonds due November 1, as well as other obligations maturing since then. The business will be continued by the receivers and an attempt to reorganize undertaken in the near future.

The total liabilities reach a substantial figure, of which, in addition to the bond issue already referred to, \$2,016,000 is said to be past due. Among the company's obligations are demand promissory notes to the extent of \$591,043.32; a note for \$300,000 due December 3, and smaller notes aggregating about \$8,000. Included in the assets are the plant, valued at \$717,498.16; finished vehicles, \$173,087.73; consigned vehicles and merchandise, \$90,387.51; patents and patent licenses, \$11,447,537.28; materials, supplies and parts in process of manufacture, \$770,474.20; stocks of other companies, \$358,002; accounts receivable, \$132,000, and cash, \$12,000, all except the last two being merely book values. Under the head of assets are also listed the "good will" of the concern and the trade name, "Columbia." No mention is made of the company's interest in the Selden patent as such.

Isaac L. Rice was the organizer of the company, but shortly afterward transferred it to the Whitney-Ryan syndicate and the Elkins-Widener interests in Philadelphia, a deal that caused speculation in the company's stock to run rife during 1899-1900, when shares sold as high as 150, being quoted just before the failure at three and five, with nothing bid. The company organized subsidiary companies in several large cities and sold or leased them the vehicles it built. The Electric Storage Battery Company, which is another Whitney-Ryan concern, is said to hold a large block of the stock.

During recent months there have been several changes in the directorate and officers. M. J. Budlong resigned as president to assume the management of the A. L. A. M., H. H. Vreeland and Grant B. Schley, Jr., resigned as directors, and Hiram Percy Maxim, who had been chief engineer of the company for the past five years, also severed his connection with it.

**MERCEDES PRODUCT TO BE MARKETED DIRECT.**

It has just been announced that the Daimler Motoren Gesellschaft, Canstatt, Germany—the parent plant of the makers of the Mercedes cars—have turned their Austrian works over to the manufacture of a car to be known as the Maja, which is new in name, but which in construction and design is a replica of the well-known Mercedes. As a matter of fact, this is a sister car of the Mercedes with all the improvements and refinements that the designers of the latter found possible, the new thing in connection with its production being the fact that it will henceforth be known as the chief output of this famous German house, and will be marketed direct in all parts of the world by a London firm. This is the Maja Company, Ltd., and with the exception of the cars sold in Germany, it will handle the entire output, the main offices being in London, with direct branches in Paris, Stuttgart, Hamburg, St. Petersburg and New York, and these branches are fully organized and already in possession of the first models, which are offered, either complete with body or as chassis alone. The New York branch is located at 230 West Fifty-eighth street, and will have an exhibit at the Importers' Salon in Madison Square Garden.

**SIXTEEN SCORE IN SEALED BONNET CONTEST.**

WASHINGTON, D. C., Dec. 10.—The sealed bonnet contest promoted by the Automobile Club of Washington and run to-day over a 118-mile course in a heavy rainstorm was by long odds the best automobile event this city has ever had. Twenty-nine cars were entered and all but three were on hand when Starter Mark gave the signal. Twenty-two cars finished within the time limit, and of this number sixteen had perfect scores. The weather conditions were enough to dampen the ardor of the most enthusiastic automobilist, as rain had been falling steadily for two days, leaving the roads in very bad condition and making fast time out of the question. To a two-cylinder Buick, driven by S. A. Luttrell, fell the honor of making the fastest time, Luttrell covering the course in 8 hours 1 minute. Notwithstanding the bad road conditions, mechanical and tire troubles were few. There were no untoward incidents to mark the contest, which was handled in a very clever manner by the committee designated by President Caverly, who was "on the job" himself.

Some portions of the route were almost impassable and required the most careful driving to bring the cars through.

Owing to the great publicity given the contest it is sure to give the trade and sport a decided impetus, particularly as there was not a single protest lodged with the contest committee. In the order of finishing, the clean-score cars and drivers were very closely placed, checking in at the final as follows:

Thomas Flyer, W. C. Hood; Franklin, E. Hart; Buick, S. A. Luttrell; Oldsmobile, J. A. Lutz; Ford, C. E. Miller; Cadillac, R. Jose; Maryland, J. M. Rife; Franklin, F. S. Bliven; Loebmobile, J. Florida; Packard, I. Freund; Wayne, John Hartman; Columbia, F. P. Hall; Mitchell, P. M. Smart; Mitchell, F. I. Flynn; Corbin, E. D. Harrison; Maxwell, J. R. Thomas.

**TO REJUVENATE PHILA-BALTIMORE "CANAL."**

MEDIA, PA., Dec. 9.—The crying need of a more direct route between Philadelphia and Baltimore than the present roundabout way through Lancaster and York was the burden of the plaint at a banquet given by the Automobile Club of Delaware County to the road supervisors and the councilmen of the several towns and boroughs of the county located along the old Baltimore, last Saturday night at the Collonade Hotel, in Media. This old road, which in the dim and misty past was macadamized, is now and has been for many years a veritable mudhole. One of the speakers, Judge Isaac Johnson, of Media, jokingly referred to the old road as a "canal," and the appellation will not come far from holding good during and after a rainy spell, frequently for many days at a time.

It was to create a sentiment in favor of an immediate improvement of the old road, which in Revolutionary days was the direct post road to the South, that the Delaware County Club gathered the supervisors and the law makers together and told them what they wanted. The seed evidently fell on fertile soil, for the club's guests were convinced that the appeal for the road's improvement was not based on a mere desire to make easy going for automobiles, but that in its present condition the highway was a detriment to the county's best interests. Besides setting the ball rolling in their own county, the Delaware Countians took steps to interest the Chester County officials in the effort to secure the rebuilding of the road as far as the State line, meanwhile working up the Marylanders to do their share in putting the road in shape up to the gates of their metropolis, as co-operation is essential to the success of the project.

As a means to the end nearest their hearts, the automobilists launched the Good Roads Association of Delaware County, and every one present pledged himself to become an active member.

The number thus enrolled in the good cause at the outset is considerable, and includes many of the most prominent autoists in the territory affected. That the most direct route between two large centers of population should have ever been permitted to fall into such ruin is inconceivable.

## DETROIT'S FIRST SHOW NOTABLE AND SUCCESSFUL

DETROIT, MICH., Dec. 10.—From an artistic standpoint the first show of the Detroit Automobile Dealers' Association, in progress at Riverview Park Auditorium this week, is an emphatic success. What it may total financially is yet to be determined, but from the attendance and the enthusiasm exhibited it is certain to prove anything but a failure.

Upwards of a score of dealers are members of the association, organized but a few months ago, and approximately twice that number of standard cars are to be seen at Riverview Park. Following as it did the national show at Chicago, Detroit got the cream of the exhibits there. In few cities is the competition keener than Detroit. In the first place it is the recognized center of automobile manufacturing, several of the largest and best known concerns in the business being located here. Outsiders were not slow to appreciate the fact that passiveness on their part would give Detroit manufacturers a decided advantage, and they have backed up their local representatives.

Many of the Chicago exhibits were sent here practically intact. Others were augmented by the factories, and, numbers considered, it would be difficult to plan a more comprehensive exhibit.

Several new features not shown elsewhere were saved for Detroit, among them being the new Ford line, including a landaulet and a five-passenger light touring car with the same chassis as the runabout. Another newcomer was an electric machine put out by the Anderson Carriage Co., of Detroit, and which made its bow to the local public Monday evening.

Manager LeRoy Pelletier was given a free hand in the decorations, and the result was a distinct surprise, surpassing any previous effort of its nature. Running entirely around the immense auditorium was a border of mammoth posters done in colors by Detroit newspaper artists, depicting humorously the experiences of motorists from the first attack of automobilitis

to the final stages of motorphobia. Green, gold and white were the colors employed in its decorations.

The show was thrown open to members of the Detroit Automobile Club for preliminary inspection Monday evening, Thursday evening being designated as society night, with the customary boost in prices. The show proved a strong drawing card, and with the final outcome yet to be determined the dealers express themselves as well satisfied.

### Gasoline Cars.

J. H. Brady Auto Co.—Peerless, Pope-Hartford and Autocar.  
Winton Motor Carriage Co.—Winton.  
Maxwell, Briscoe, McLeod Co.—Maxwell, Mitchell and Brush runabout.  
J. P. Schneider—Pierce, Stevens-Duryea, Franklin, Pope-Toledo and Columbia.  
Wm. F. V. Neumann & Co.—Welch, Stoddard-Dayton and Reo.  
Grant Bros. Auto Co.—Thomas Flyer, Thomas Detroit and Buick.  
Cadillac Motor Car Co.—Cadillac.  
Anderson Electric Agency—American Simplex.  
Fee-Bock Co.—Elmore.  
Ford Motor Co.—Ford.  
Seldner-Miner Automobile Co.—Jackson.  
Motor Car Co.—Cartercar.  
De Luxe Motor Car Co.—Car De Luxe.  
Oldsmobile Co.—Oldsmobile.

Fee-Bock Co.—Pope-Waverly.  
Fee-Vincent Co.—Woods Electric.  
J. P. Schneider—Columbia.  
Seldner-Miner Auto Co.—Babcock.

### Steam Cars.

White Sales Co.—White Steamers.

### ROADMAKERS TO HEAR BAY STATE AUTOISTS.

SPRINGFIELD, MASS., Dec. 9.—A movement has been started by the Good Roads Committee of the Automobile Club of Springfield which is likely to result in the installation of continuous State road between this city and Warren, the practically sole remaining link of poor road on the trunk line between Boston and New York. A hearing will be held in this city, Thursday, December 19, when the State Highway Commission will hear prominent autoists from the western part of Massachusetts, where the Berkshires are located.

In addition to the completion of the trunk line which will be brought up, the autoists will insist on the completion of at least one of the three routes from Springfield into the heart of the Berkshires, one of the most popular goals for autoists as well as the most beautiful of its kind in New England. Of the three routes from Springfield, via "Jacob's Ladder," Becket, and Northampton, the "Jacob's Ladder" route has only about eight miles of uncompleted road, and this route also Chairman McClintock has signified an intention to complete next spring.

It is the opinion of autoists in this part of the State that this immediate section has been neglected by the State Highway Commission for the last year or two, and for this reason Chairman McClintock announced at the Good Roads convention, held here in September, that he proposed to remember it in the road construction next year.

The committee of the Automobile Club which has the details of the hearing in charge consists of Willis A. Ford, chairman; Superintendent of Streets Arthur A. Adams, and W. T. Helfer. The visiting autoists and the members of the Commission will be entertained here by the Automobile Club.

### MOTORPHOBE JUSTICE OVERSTEPS HIMSELF.

ALBANY, N. Y., Dec. 10.—That a too zealous upholder of the speed laws may defeat his own ends by imposing limit sentences, has seldom been better illustrated than in the case of Howard A. De Graaf, who was arrested for overspeeding in Rensselaer county, and taken before Justice J. P. Van Ness in the village of East Greenbush, N. Y. He pleaded not guilty and was fined \$100, from which decision he appealed. The action, known as *People vs. De Graaf*, was defended by Bender & Hinman, of Albany, and was carried to the County Court, which recently handed down a decision that not alone reverses the lower court, but effectively puts an end to any further proceedings. A justice's court is not one of record, and, as such, its jurisdiction is limited to imposing fines not exceeding \$50 nor terms of imprisonment not exceeding six months, so that in fining Mr. De Graaf \$100, Justice Van Ness, who has achieved quite a reputation as a motorphobe, exceeded his authority, notwithstanding the fact that the Motor Vehicle law provides for a maximum fine of that amount. In similar cases of error the appellate court has the power to remit the record to the trial court for correction, but the statute does not include courts not of record, so that the action can go no further.

### POPE RECEIVERS HAVE POWER.

TOLEDO, O., Dec. 9.—Judge Tayler, of the United States Circuit Court, has come to the assistance of A. L. Pope and G. A. Yule, receivers for the Pope Motor Car Company, of this city. Upon application by the receivers, in re the case of MacManus-Kelly company, the court granted the privilege to borrow additional money, issue more receivers' certificates on a changed basis and to renew the certificates issued August 18.

# AUTOMOBILE LAMPS AND THEIR LENSES

By VICTOR LOUGHEED.

THE average purchaser of an automobile lamp makes his selection more on the lamp manufacturer's reputation than he does on any knowledge of his own concerning lamps. Indeed, more often than not it is the opinion even of the automobile expert that all lamps are pretty much alike and afford little room for the engineering refinements and niceties that are a matter of course with the more complicated car itself. Finish and workmanship, as well as the price, are expected to vary, but such nice optical distinctions as the difference between a "parabolens" and a "paraboloid" might as well be non-existent for all the attention they attract from the people most interested in their merits and applications, while the seemingly trivial difference between a short-focus and a long-focus lens mirror is almost never appraised at its full value. Yet a very cursory incursion into the field of the lamp maker is sufficient to convince the discerning layman that there is an XYZ as well as an ABC to the apparently simple proposition of providing a source of light and directing the illumination in a desired direction.

ities, and the incandescent gas lamp, which by the use of the new hard mantles, in conjunction with gasoline-vapor burners, should even now be capable of giving as good service on automobiles as it is giving in railway coaches and in other commercial uses.

The value of a light is usually expressed as so many "candlepower"—one candlepower being the light photometrically determined as that given by a sperm candle of certain standard size and construction. With most lights the illumination is radiated in all directions, though not necessarily with uniform intensity. This condition has given rise to the term "mean spherical candlepower," by which is meant the total of the light from a given source which will fall on the interior of a hollow sphere of a given size, as suggested by the cross section of *B*, Fig. 1, the source of light being at *A*. The necessity for basing figures upon a sphere of standard size is easily perceived when it is considered that to make the sphere larger or smaller will increase or decrease the surface and thus correspondingly increase or decrease the illumination to a given unit of area. Thus, to

FIG. 1.—Illustrating the method of measuring "mean spherical candlepower," the light being placed at *A*, while the standard sphere through which the light is thrown is represented by *B C*, in the form of a hollow truncated cone.

FIG. 2.—Showing how the amount of light available depends upon the form of the container in which it is placed, the box shown here permitting only 12 per cent. of the total light of *A* to be utilized, while 88 per cent. is absorbed and lost.

The illuminants so far developed as practical for automobile lamps are few in number. There is the common kerosene-oil burner—simple, reliable, economical and universally available, which gives good service in a multiplicity of cheaper constructions; there is acetylene—affording a brilliant flame of great power, capable of being readily maintained from either a generator or storage tank; and there is electricity, in the form of the incandescent lamp, giving a light that is more nearly ideal than most others, though the problem of supplying it with current is not as simply and inexpensively solved as with its competitors. In addition to these there is the oxy-acetylene calcium light, which has been developed in a small way, but with considerable success, abroad, and in which a flame of acetylene fed with oxygen from a special storage tank is directed upon a lump of lime, giving a dazzling light similar to the well-known limelight, save for the substitution of acetylene for the hydrogen used in the earlier system. In the way of possibilities that may perhaps be considered as verging on commercial success, though they have not yet achieved it, there are the electric arc lights, developed to a high degree of efficiency for railway car use, the Nernst electric light, possessed of some alluring possibil-

ities, and the incandescent gas lamp, which by the use of the new hard mantles, in conjunction with gasoline-vapor burners, should even now be capable of giving as good service on automobiles as it is giving in railway coaches and in other commercial uses. This law holds good in all possible applications and for parts of spheres as well as whole spheres, so it is the comparatively simple explanation of the fact that the intensity of light decreases in proportion to the square of the distance—being only one-fourth as intense for twice as far, one-ninth as intense for three times as far, one ten-thousandth as intense for one hundred times as far, etc. The last figure is suggestive of the problem encountered in lighting the road in front of an automobile, since to get a given illumination 1,000 feet ahead, ten thousand times as intense a light is necessary as would be required to give the same illumination ten feet ahead.

It is obvious that there are just two ways to overcome the difficulty stated. One is to adopt the absurd policy of actually providing the light of a strength ten thousand times multiplied, with all that this would involve in the way of costly and complicated maintenance, objectionably intense nearby illumination, at the same time cutting off rays falling in undesired directions.

The other method is to utilize a light of more moderate power while intercepting its rays of undesired direction by mirrors and lenses, properly formed to reflect and refract the largest possible proportion of these rays into the direction in which the illumination is required. In this connection it must be understood that light rays always travel in straight lines from their source, unless reflected or refracted, so a lamp consisting of simply a vessel of non-reflecting material, with an opening in one side, would waste a majority of the light just as completely as an entirely closed vessel would waste the whole of it. That is to say, if the opaque, non-reflecting vessel *B*, Fig. 2, is used for a lamp, all of the light from *A* that would have fallen on the spherical surface *C D E* is wasted, only the cone of light *C E*, amounting to only 12 per cent. of the total from *A*, being saved.

FIG. 3.—Type of characteristic automobile headlight using long-focus mirror lens, showing the manner in which the light given by *A* is concentrated and thrown directly forward in the shape of parallel rays.

And it is projected in diverging rays, producing an illumination of rapidly diminishing intensity, in accordance with the law already stated in connection with lighting objects at a distance.

From what has been explained, it now must clearly appear that for a light to be projected to a distance without exceedingly great loss it must be projected in a beam of rays as nearly as possible parallel. And to give as powerful an initial intensity as possible to the beam all rays from the light source that can be reflected or refracted into it should be intercepted by mirrors or lenses, or by a combination of both. The nearest possible approximations to these ideal requirements are the ends sought by all scientific lamp manufacturers.

#### Low Efficiency of Typical Auto Headlight.

A characteristic automobile headlight, using a long-focus lens mirror, *B*, is diagramed in Fig. 3, in which *A* is the source of light, *C F* is the cone of rays intercepted and projected by the mirror, and *C D E F* is the amount of light wasted. In this case, with the proportions pictured, the amount of light, *C D*, which is converted in the parallel beam *D E* is only 12 per cent. of the total given by *A*.

A short-focus lens mirror lamp is diagramed in Fig. 4, in which the principal difference from the preceding consists in shaping the lens mirror *B* so that it can be placed closer to the light at *A*, this simple expedient serving to increase the size of the cone of intercepted rays, *C F*, very materially over that of the corresponding cone in the preceding case, 37 per cent. against 12 per cent. of the light now being saved, which amounts to an actual tripling of the forward illumination as represented by the beam *D E*.

Before proceeding further it will be well to explain some of

the considerations involved in the reflection and refraction of light under the conditions that apply in an automobile lamp. To begin with, it must be known that the ideal illumination for projection purposes would be one with all the light proceeding from an infinitely small point, no other condition permitting the realization of a perfect non-diverging beam of maintained intensity. Practically, of course, it is impossible to realize this theoretical ideal, but the best results are had with the lights that nearest approximate its requirements. Incandescent electric lamps, for instance, with closely coiled filaments, and the oxy-acetylene light, with a small button of lime as the source of the illumination, give good results, while the tiny "crater" of an arc light, whence nearly all of its light emanates, is the reason for its universal use in navy searchlights. Reflecting surfaces are invariably metallic, properly polished speculum metal, composed of 70 parts of copper to 30 parts of tin, reflecting a greater percentage of the light than anything else that is in practical use. Next to this comes the amalgams with which the backs of glass mirrors are coated, while pure silver is a close third in its qualities.

#### Every Surface Absorbs Some of the Light.

No surface, of any material, can reflect all of the light that falls upon it, some certain proportion, varying from very little in the case of a good mirror to almost the whole in the case of a dead black surface, being absorbed. This makes it imperative that reflecting surfaces be kept in a condition of highest possible polish, if a major portion of the light falling upon them is not to be lost by absorption. To keep them so, however, when exposed to dust, soot and the heat of a burner, is no simple problem, for which reason the mirror lens, practically a glass protected film of metal employed as a reflector, has come widely into use, it being comparatively easy to keep the glass clean.

It is a law of optics that a ray of light falling upon a surface is reflected at the same angle as that at which it impinges—the "angle of incidence being equal to the angle of reflection." This

FIG. 4.—Short-focus lamp of type similar to that shown in Fig. 3, illustrating the saving effected by bringing the mirror reflector closer to the source of light, the efficiency of this lamp being more than triple that of the former.

law controls the form of mirrors, and, because of its mathematical properties, a paraboloid—the figure formed by the rotation of a parabola on its axis—with the light at its focus, is the only form of mirror that can project in an absolutely parallel beam all of the rays that fall upon it. A parabola, however, is a curve that can be infinitely extended—being mathematically an ellipse with its other focus at infinity—so it follows that a parabola of any desired size can be used, extended to any desired degree. This makes it practical to use spherical mirrors

with a close approximation to theoretically correct results, provided the pencil or cone of rays intercepted by the mirror does not make too great an angle—the first portion of a parabolic curve conforming very close to an arc of a circle. In fact, the divergence given to the beam of light by the judicious use of a spherical mirror with a full understanding of its limitations is sure to be very much less than that unavoidably occasioned under any circumstances by the size of the light, which always must occupy more space than the theoretically ideal point.

In the use of mirror lenses the phenomenon of refraction, as well as that of reflection, must be taken into account. Refraction is produced whenever a ray of light passes from one transparent medium into another denser or rarer, and consists in a bending of the ray at the point of contact between the two media. The amount of this bending varies with different substances, each having its index of refraction, so by the use of properly shaped lenses of suitable materials refraction affords an important means of collecting or dispersing rays of light. A mirror-lens reflector necessarily has two surfaces—one to which the reflecting coating is applied and one that is left clear. The light striking this latter surface, therefore, undergoes refraction before it is reflected, and is again refracted as it emerges to produce the beam of light. This double refraction of the light rays would seriously disturb the results, even though the reflecting surface were of true parabolic form, were it not taken into account and the refracting surface of the lens given a properly related form. It is this consideration that explains the usual thickening of lens mirrors from their centers to their edges.

**Character of the Light Limits the Focus.**

Since the possible shortness of focus in an ordinary automobile lamp is limited by the danger of breaking the lens by the heat of the flame, despite the general use of heat resisting lead glasses, it follows the larger the mirror the larger the cone of rays it can intercept and reflect. This is because the minimum possible focus being determined by the heat condition

FIG. 5.—Combination of mirror lens with paraboloid reflector, by means of which fully 50 per cent. of the light produced by the burner at A is utilized in the rays thrown directly forward between G and F.

rather than by any optical condition, a given focus is shorter in proportion to a large lens mirror than it is to a small one.

Thus, in Fig. 4, if the lens mirror shown were replaced by one of larger size the cone of light falling upon it would be larger than that from C to E, with a corresponding increase in the light from A reflected to the beam D E. This would, of course, also increase the size of the beam, but in a less proportion than the increase in light reflected, so there is a gain both in intensity and in area illuminated. Evidently, then, it

pays to have as large a mirror lens as can be afforded. With mirror lenses the waste of light C D E F, Figs. 3 and 4, is a serious objection, especially with flames like an acetylene flame, which gives practically equal light in every direction, and many attempts are made to overcome it. With a light like that of the electric arc, from which most of the light proceeds in one direction, the objection is not so pronounced, as by inclining the carbons most of the illumination can be cast on the mirror.

The lamp diagramed in Fig. 5 is a very common combination of mirror lens B with a portion of a paraboloid reflector D E H I. By this combination only the light from E H and I J is lost, the amount saved being increased to 50 per cent. of the whole, against 12 per cent. in Fig. 3 and 37 per cent. in Fig. 4. An objection to it is that the supplemental mirror E D H I

FIG. 6.—Common type of locomotive headlight with metal paraboloid reflector, using no mirror lens, as in automobile headlights. This lamp has a net efficiency of 88 per cent., but the metal reflector condemns it.

must be made of unprotected metal, and that, as such, it will either tarnish to a most inefficient condition or else present all manner of frequently recurring difficulty in the way of keeping it finely and serviceably polished. Moreover, such polishing, even if successfully accomplished—which is scarcely possible outside of a factory—will gradually wear away the exactness of surface that is a first essential to service.

Fig. 6 shows a regulation paraboloid lamp, with metal reflector, to the exclusion of the mirror lens. This type of lamp is used on nearly all locomotive headlights, and projects, with the proportions shown, 88 per cent. of the light—more than in the case of any of the preceding. But with it the objections to metallic reflectors are more than ever present, and especially condemn it for automobile use, which involves carrying it close to the ground, giving dust and moisture every opportunity to cause trouble. Some electric automobile headlights, however, are built on this plan and give a minimum of trouble because of the absence of any flame, but as already outlined the electric is not yet generally available for automobile use.

**“Parabolens” Has the Highest Efficiency.**

To gather in the rays C F, Fig. 6, which are the only ones that escape reflection in a paraboloid lamp, the “parabolens” lamp, illustrated in Fig. 7, has been devised. This design, which is a good many years old, having been first applied to locomotive headlights, was first adapted to automobile use in Europe. It intercepts 100 per cent. of the light and, were it not for the objections seemingly inseparable from the use of metal reflectors, would be far and away the best of all possible lamps. Its especial feature consists in the use of the lens Q to intercept the cone of light C F that escapes in Fig. 6. The use of the lens

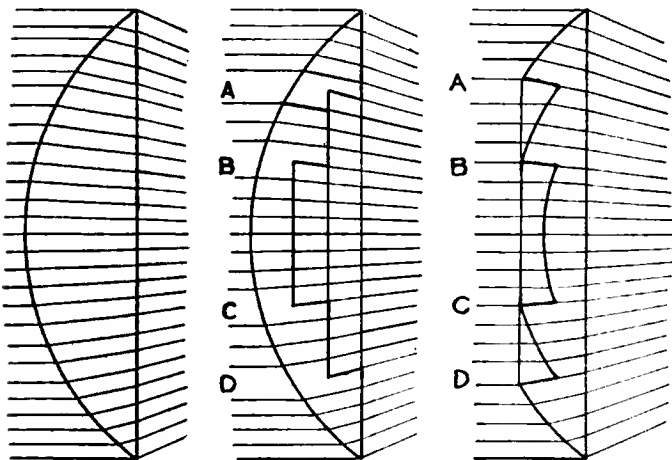

FIG. 7.—"Parabolens" type of lamp, formerly used on locomotives and first successfully adapted to the automobile on the Continent. It consists of a spherical reflector and plano-convex lens.

also requires a modification in the paraboloid reflector, the portion from *R* to *S* immediately behind *Q* being made spherical. This is because this portion of the reflector is not now required to cast parallel rays directly forward, since the only rays that the lens *Q* can project forward are ones that radiate upon it from a focus at the light source *A*. Therefore, by the use of a spherical reflector at *R S* each ray of light falling upon it from *A* is reflected directly back through *A* and thence to *Q* or *B*, just as in the case of the unreflected rays from *A*.

#### Preventing Absorption of Light by the Lens.

Since the lens *Q* has to be of considerable thickness, if of the ordinary plano-convex form shown in Fig. 8, which results in a considerable portion of the light passing through it being lost by absorption, the expedient of cutting back the plane surface of the lens as shown in Fig. 9 and 10 can be adopted, with the effect of thinning the glass while in no way adversely affecting the optical properties. Because of the difficulty of grinding the mortise-like depressions in Fig. 9, it is more usual to cut back the curved surface, as shown in Fig. 10. Both of these methods possess the minor objection that they give the dark zones at *A*, *B*, *C* and *D*, but there is enough diffusion of the light, because of the size of the flame, to fill up the dark zones before the beam is more than a foot or so from the lamp. Indeed it is difficult to discern their shadow on a sheet of paper unless it is held very close, though theoretically they should be totally black.

FIGS. 8, 9 and 10.—Illustrating the various expedients adopted to prevent loss of light by absorption in the glass of the lens itself when used in connection with the "parabolens" lamp as described here in detail.

Lamps of the parabolens type are best with chimneys surrounding the flame, to protect the reflecting surface as much as possible from heat and soot. Of course, with incandescent electric lights this precaution is especially unnecessary, and it is probable that this type of lamp, with electric light, will become increasingly important in the future. This seems especially likely to become the case in view of the recent developments in the incandescent lamp field, whereby a current consumption as low as one watt to the candlepower suffices for the operation of metallic-filament lamps, against the three-and-one-half-watt consumption of the ordinary carbon-filament lamp. It has even been suggested that with electric lights some method might be found of exhausting the air from parabolens lamp interiors. This certainly would be a means of avoiding the tarnishing of the reflector, but its practical application would involve some means of inserting lamp renewals besides absolute prevention of leakage.

#### How a Lamp's Candlepower Is Calculated.

It is to be noted, in considering the merits of the parabolens construction, that the lens *Q* will easily intercept as large a cone of rays as is intercepted by the long-focus mirror lens in Fig. 3, for which reason it is better than this type, even with its reflecting surfaces so tarnished as to be practically out of commission. In statements of the quality of projecting lamps it often will be seen asserted that the candlepower is 3,000 or some similarly high figure. In this case it is meant that the normal candlepower of the light, multiplied by the quotient given by dividing the area of a complete sphere by the area of the beam, gives this figure. For example, in Fig. 7 the entire light that normally would fall from *A* on the spherical surface is concentrated, minus absorption losses, into the area *D E*. This area is only one-fiftieth of the total area of the spheres shown, so the intensity at this unit distance is multiplied fifty times. Now, if *A* be a 25-candlepower burner, which is the usual acetylene or electric light standard, 25 times 50 gives 1,250 candlepower as the measure of the intensity of the beam. Front glasses for lamps are best when made of plain circular panes of thin plate glass, but to prevent breakage by expansion it is necessary, in very large lamps, to cut the front glasses into narrow vertical strips, capable of individual adjustment to temperature changes.

Enough has been said, it is hoped, to convince the reader that in the purchase of lamps, as well as of other automobile accessories, one gets about what he pays for, and that behind high prices there may be skill and quality far beyond what can be present in similar appearing goods sold at lower figures. Cheap mirrors and lenses usually are of molded glass, while the better qualities are ground; cheap metal reflectors are stamped, or spun, and roughly polished, while the best ones are finished more accurately by turning; back-opening lamps, to facilitate the cleansing of mirror lenses, are a convenience that can be had if paid for; and stop-cocks to adjust to a nicety the flames of twin headlights cost about what they are worth. The point is, every construction has its merits and serves its purposes, even if these be chiefly the meeting of the various classes of demand that exist. The discriminating buyer, considering his needs and his pocketbook, and knowing what is to be had, purchases accordingly, but, as has already been made plain, there is possibly not one in a hundred, or probably the proportion could more truthfully be lowered to the familiar "one in a thousand," in the ranks of present-day automobilists whose knowledge of lamps or the laws of optics is of sufficient extent to fit him to make such a choice intelligently. In the slang of the day, it is merely a case of "you pay your money and take your choice," but the choice is always influenced by the price set upon the article by the maker, and one of the chief objects of the foregoing has been to indicate that the added cost is by no means merely a matter of finish, or that the buyer is simply paying for the maker's name and nothing more, as has been the case only too frequently with many other lines of automobile accessories in general use on American cars.

## LETTERS INTERESTING AND INSTRUCTIVE

### TWO WHO THINK THE ACCIDENT AVOIDABLE.

Editor THE AUTOMOBILE:

[1,000.]—The accident illustrated and described by A. L. Westgard, in your issue of November 28, was, to my mind, avoidable, and was due to incompetent chauffeurs, particularly the one on the Broadway car, who should have stopped when the street car did and not attempted to cross Sixty-second street, when he had not seen if the way was clear. The fact that the street car stopped on that side of the street showed the way was not clear. It is an axiom of competent chauffeurs not to cross any street or in front of street or other cars without knowing absolutely the way is clear.

New York.

Editor THE AUTOMOBILE:

[1,001.]—Referring to Mr. Westgard's letter, No. 986, in your issue of November 28, concerning the accident at corner Broadway and Sixty-second street, I should say that this accident was the fault of "B." It is the common rule of the road that traffic on main thoroughfares and boulevards, and north and south streets have the right of way, and traffic coming in from cross or side streets or roads should approach or cross the thoroughfares cautiously. Certainly Broadway in this case is the main north or south thoroughfare, and any one coming in from Sixty-second street should come in with great care. What does your legal department think of this?

Chicago, Ill.

While not disputing your contention that the accident was avoidable, we might add that the fact that the street car stopped at that side of the intersecting street could not be taken as evidence that the street was not clear, as a municipal ordinance compels all street cars to come to a halt on the near side of a cross street in which a fire department station is located. If the street car had not come to a halt there would have been no accident, as B did not attempt to cross until he saw that the car's stopping left the way clear for him to get over the track.

Regarding the second letter, the statement that the traffic on avenues or other principal thoroughfares has the right of way is quite correct; also that drivers coming in from side streets should exercise greater care to avoid avenue traffic. But this being granted, it does not necessarily follow that B was at fault. In all such cases, when considered from the purely legal point of view, the responsibility for such an accident would depend upon whether the alleged cause of it were guilty of negligence or not. One of the chief elements of negligence is failure to exercise reasonable care, and just what constitutes the latter has been the subject of an endless number of decisions, as it depends entirely upon the circumstances governing the case. Broadway is quite a wide thoroughfare at the point in question, consisting of two roadways and a dividing walk down the center, and as B found it possible to cross two-thirds of the thoroughfare without seeing any other obstruction than the street car, the stopping of which permitted him to pass in front of it, the conclusion that he did not use reasonable care under the circumstances would not appear to be altogether well founded, as reasonable care does not imply the utmost precaution, but what the average man would do under the circumstances.

### TWO-CYCLE CRANKCASE VOLUMES.

Editor THE AUTOMOBILE:

[1,002.]—In a two-cycle engine, which gives the greater charge in the cylinders—a crankcase of small capacity, or one of large capacity?

ELMER NEWTON.

San Antonio, Texas.

The small volume crankcase, of course, gives the greater charge because it gives the higher crank chamber compression, with the consequent forcing of more fuel through the by-pass. The amount of fuel inspired under the piston is determined by the bore and stroke of the piston, and a large crankcase, therefore, cannot increase the amount inspired, while by lowering the crankcase compression it reduces the volume transferred.

### TEMPERATURES AND CYLINDER WALL DAMAGE.

Editor THE AUTOMOBILE:

[1,003.]—Kindly advise me through "Letters Interesting and Instructive" at what temperature of the surrounding air will water, contained in jackets of automobile engine cylinders, freeze sufficiently to crack or burst the jackets. Please give me some information regarding water in copper fire-tube boilers, such as used in the Stanley steam automobiles. In both above cases, motor and boiler entirely cold and not receiving any artificial heat. Will water expand any in water-jackets at surrounding air temperature of 32° above? Will water, or ice formed from it, expand any more at temperatures of surrounding air lower than 32° than at 32°? Is it extremely cold water that bursts pipes, or must ice form before bursting occurs? "A SUBSCRIBER."

Newburgh, N. Y.

The same as if it were not contained in the water-jackets of an engine cylinder—i. e., 32 degrees Fahrenheit or zero Centigrade—assuming it to be ordinary fresh water, of course. You neglect to take into consideration the time element, as, assuming the temperature in question, several hours might be required to reduce the surrounding iron and the water itself to that temperature before freezing would take place. It would also require some time for the entire body of water to freeze or become solid to an extent where it would cause the bursting of the water-jackets. The water does not expand of itself, still remaining liquid, but in forming ice occupies 8.55 per cent, greater space than it did in the liquid state, and having once become ice it does not expand to any greater extent, regardless of the drop in temperature. Ice must form before any damage is done, otherwise anti-freezing solutions would be worthless, as it is only their property of remaining liquid at low temperatures that acts as a protection to the cylinder in preventing freezing.

### MERITS OF DIFFERENT IGNITION SYSTEMS.

Editor THE AUTOMOBILE:

[1,004.]—What is the difference between high tension and low tension? Which is the most expensive to install? Which is the most expensive system to maintain? Which is considered most reliable?

Hartford, Conn.

In the high-tension system the current, when supplied by a battery, is led through a timer, the contacts on which correspond to the different cylinders. As contact is made in the timer the current is sent through the primary winding of an induction coil, which transforms or "steps it up" to a very high potential, thus enabling it to jump the gap of the spark plug, from which the name "jump spark." There is a coil for each cylinder usually, though in what is known as the "synchronized" system a single coil is employed, the primary current being timed and the secondary current distributed synchronously. In brief, the foregoing represents the high-tension system as generally employed, though there are various modifications.

Except for stationary or slow-speed work, it is not practical to use the low-tension or make-and-break ignition with a battery, but when so employed the current is first sent through what was commonly known as a "spark coil" before autoists applied the same term to the now generally used induction coil. The spark coil is merely a plain winding of heavy wire on a large core, and by what is known as self-induction causes a larger spark to take place when the ignitor opens. On automobile work the low-tension system is used with a magneto exclusively, no coil being necessary. The current generated in the magneto is led to an insulated plug inserted in the cylinder, against which a small moving arm makes contact through the medium of a push rod and cam on the camshaft of the motor. The current employed is low-tension, low voltage, or low potential, all of which mean the same thing, and consequently will not jump a gap. Hence in most ignitors, which take the place of the spark

plug in the high-tension system, the circuit is closed until the moment the spark is to take place, when the arm is snapped away from the stationary member, causing the current "to arc" or flash at the rupture of the circuit, the magneto being so timed that the current impulse generated is at its highest value just at that particular moment.

The low-tension system is without doubt the most expensive system to install, despite the fact of its far greater simplicity, as it requires a high-priced magneto and the work on the motor itself is of an expensive nature, the fact that the latter was done cheaply and without due regard to the requirements of the high-speed motor causing this system to be regarded unfavorably in early days. The high-tension system is the most expensive to maintain, particularly where batteries are employed as the source of current. Theoretically, where a high-tension magneto is employed alone this system should have the advantage in cost of upkeep over the low-tension, but we doubt if this proves to be the case in actual practice. The high-tension magneto, particularly of the self-contained type, is far more liable to derangement than the simple low-tension generator, while the cost of spark plug replacements will doubtless considerably exceed the expense of keeping the low-tension ignitors in shape. The question of reliability is one on which there is a great deal of difference of opinion, but we incline toward the low-tension system, owing to its far greater simplicity and corresponding certainty of action.

#### CONCERNING VARIOUS CHANGES OF GEAR RATIO.

Editor THE AUTOMOBILE:

[1,005.]—I have a two-cylinder machine which was originally geared 10-32, which I considered too high. I had it changed to 10-36, which worked very satisfactorily. Recently I had to order a new rear sprocket and they couldn't furnish the 36, but sent a 38, and, rather than wait, I had the 38 put on, but the machine is too slow. Now, would it not be better to put on a 11-tooth engine sprocket and leave the 38 on? Will you give me the ratio of increase of power between the 10-32 and the 10-36, and the 11-38? Road wheels, 28 inches.

F. P. SNYDER.

Lafayette, Ind.

No matter what changes were made in the gear ratio of the transmission, this would not affect the power of the engine in any way, though it naturally has a very important bearing on the engine's ability to move the car, particularly on grades, as well as on the speed. The first gear ratio which you found too high was 3.2 to 1, and the second 3.6 to 1, and the third 3.8 to 1, and as the 28-inch wheels of the car only cover 7.25 feet per turn this last gear ratio would give the car a speed of but little better than twenty miles an hour on the direct drive, assuming that the engine ran at the rate of 1,000 r.p.m., so that we do not wonder you find it rather slow. Using an 11-tooth sprocket forward will give a result between the 10-32 and the 10-36, namely 3.45 to 1, and we should think this would be even more satisfactory than the 10-36 combination.

#### WHAT CONSTITUTES RUNNING TIME ON ROAD?

Editor THE AUTOMOBILE:

[1,006.]—Being a constant reader of your interesting journal for the past three years, would like to know if you would kindly give me some information in your columns, under the heading "Letters Interesting and Instructive," to settle an argument and wager. What do you consider running time on road? To be delayed by teams or other obstructions or stopping for meals, would you figure this as running time, or not?

G. D. W.

Butte, Mont.

Time consumed in stopping for meals is naturally not actual running time and should not be figured as such. With regard to being delayed by obstructions, it would depend somewhat upon the manner in which this was done. If the obstruction were such that the car had to be halted until it was removed, the resulting delay would not ordinarily be included in the actual running time, but where the car is pocketed behind a slow-moving team or something of the kind, but continues to move, though at a greatly reduced rate of speed, this would be figured as running

time. This is our impression of the general usage; on railroads, however, we believe it is customary to term the entire time allowed to make the run, including all regular stops, as a train's running time. In most automobile contests just what shall constitute running time is agreed upon in advance and includes everything but stops for meals and for tire repairs, as a rule.

#### CREDIT FOR FIRST SIX-CYLINDER MISPLACED.

Editor THE AUTOMOBILE:

[1,007.]—In answer to Mr. Titus' letter in the issue of "The Automobile" of November 7, in regard to the first six-cylinder car offered for sale, I wish to state that in the early part of 1904 the Commission Auto Company, of Boston, Mass., sold to a party in Attleboro a six-cylinder Gasmobile. This car at that time was second-hand and had been run a number of thousand miles and was surely over a year old. This car had a six-cylinder vertical engine, valves and spark plugs in the cylinder heads, leather-faced cone clutch, four-speed Panhard type transmission, and side chain drive. If the Thomas engine was built in 1904 and the Stevens and Napier in 1905, I am very sure that the Gasmobile Company have a very strong claim on building the first six-cylinder engine. This car can undoubtedly be seen to-day in Attleboro. Possibly somebody connected with the Gasmobile Company can give us the exact date that this car was built.

C. T. BATES.

Brockton, Mass.

The car you refer to was built after designs by Fisher & Otto and was exhibited at Madison Square Garden in 1901 or 1902, and as a year or two was a long time in the early history of the automobile, counting by the progress made, the interval elapsing between the exhibition of this first six-cylinder and those of later vintage, was probably sufficient for many to have forgotten the pioneer, while later comers would naturally not be in a position to know of it.

#### SOME FACTS CONCERNING DENATURED ALCOHOL.

Editor THE AUTOMOBILE:

[1,008.]—Will you kindly advise me through "The Automobile," of which I have been a constant reader for some years, if the duty has been taken off grain alcohol; if so, when, and what is the retail price in New York City?

ARTHUR HENDEY.

Jerome, Ariz.

The bill exempting grain alcohol from internal revenue tax when properly denatured according to government specification went into effect on January 1, 1907, and an amendment to the bill took effect in July last. This, of course, only applies to grain alcohol that is rendered unfit for drinking purposes by the addition of some noxious substance, such as wood alcohol. The retail price in New York City is about 60 cents a gallon upward, according to where it is purchased.

#### SINGLE COIL SYSTEMS OF IGNITION.

Editor THE AUTOMOBILE:

[1,009.]—Will you please answer, through your "Letters Interesting and Instructive," why a single coil wired so as to supply sparks to each cylinder of a motor is not better than multiple coils, since the spark would be uniform in each cylinder, and hence the motor would run steadier? If you have room, could you also give a diagram for the wiring of a single coil to supply a two-cylinder, two-cycle motor?

INTERESTED SUBSCRIBER.

Boston, Mass.

The chief difficulties in the past, where the use of a single coil was concerned, were not so much with the coil itself as with the distributor of the secondary current. It was found so hard to properly insulate this that the use of a single coil and distributor, which had been adopted by quite a number of makers several years ago, was almost universally abandoned. Improvements in distributors have caused it to be taken up again, however, and it is now successfully used on quite a few cars. A modification of the idea is also employed, in which the four unit coils are used, but without vibrators, a fifth vibrating coil, or "master vibrator," being utilized to synchronize their action.

The wiring of such a system is so simple as to scarcely call for a diagram. A distributor designed for a two-cylinder, two-cycle motor must be obtained, and taking this as a starting point,

carry two high-tension wires from its secondary terminals, one to each of the spark plugs. Connect the primary and secondary terminals of the distributor with the corresponding posts on the single coil, these terminals usually being marked to enable this to be done without any trouble, in addition to which the manufacturers generally provide explicit directions. One side of the battery should be connected to the primary terminal of the coil and the other side of the battery grounded. As already mentioned, one side of the secondary of the coil is connected to the distributor; the other is grounded.

HOW THE 20-30-HORSEPOWER RENAULT CHASSIS

**R**EGARDED externally only, it would require an expert to distinguish between the models produced by the Renault Frères or the 1908 season and those turned out of the Billancourt factory during the past year. This settling tendency, general throughout the automobile industry, is probably more pronounced in the Renault product than in any other of Europe or America; it is indeed a boast of the firm that between their smallest touring car and their most powerful racer there is no difference other than that of size.

Commencing with the small two-cylinder engine...

#### WEATHER CONDITIONS FOR EUROPEAN TOUR.

Editor THE AUTOMOBILE:

[1,011.]—Can you give me any information as to the climatic conditions of a tour through Italy and France up to the British Isles, in February and March? JOHN D. HORGAN.  
LYNN, MASS.

Throughout the south of France and the lowlands of Italy climatic conditions are favorable for touring from the middle of February. Even along the Mediterranean coast, however, one may expect occasional cold spells until March, and the mountain districts cannot offer many attractions to the automobilist before April. From Paris northward cold weather and considerable rain may be expected during February. Usually towards the end of March climatic conditions have sufficiently improved to make touring agreeable. February and March are invariably disagreeable months for touring in the British Isles. Even in the south of England no vegetation has appeared at the end of March, and in the northern counties and Scotland stormy weather with rain or snow may be looked for until April. To obtain best climatic and touring conditions we would recommend staying in Italy or on the French Riviera until the end of March, visiting the northern part of France in April and the British Isles in May, thus following the warm weather northward.

#### AN UNUSUAL TYPE OF MANIFOLD.

Editor THE AUTOMOBILE:

[1,012.]—I would like to have you, through "Letters Interesting and Instructive," help me out of my trouble. I have an auto driven by a two-cylinder opposed motor. This motor starts hard. It has to be cranked for some time before it will take a charge. After starting it runs smooth and very slow speed, say 300 r.p.m., but when speeded up to about 500 or 600 it misses badly, but again works well at 800 or 900 r.p.m., and at any time it does not miss when pulling hard. My carbureter is set about four feet from the manifold, the tube leading from the carbureter is 1 1/4-inch iron tube, it goes down from the carbureter about six inches, then on a level, and then straight up to the manifold. There is a drip hole at the lowest place in this pipe, and after running the machine clean gasoline will run out of this drip. Is this caused

by the long pipe that the mixture goes through or by the carbureter being set wrong? The carbureter is a Schebler, and air valve is set as weak as possible and the gas jet about 7-8 of one turn open. I can set the carbureter at the center of the manifold. Do you think this would help?  
R. H. DOW.  
Adrian, Minn.

The position of the carbureter is most unusual and is apparently the cause of the difficulty you detail. The fact that a portion of the manifold is beneath the carbureter level doubtless sets up a siphon action, causing liquid gasoline to flow into the lower part of the manifold, which would account for the erratic running at low speeds or when the demand on the power is light. When the motor is running loaded the manifold becomes heated and the extra suction prevents the gasoline which finds its way into that part of the piping from remaining liquid. Relocating the carbureter at the center of the manifold and placing it so that no part of the piping is below it would doubtless be found to remedy the trouble.

#### ABOUT THE EMPLOYMENT OF PRESS FITS.

Editor THE AUTOMOBILE:

[1,013.]—Why is it not practicable in automobile construction to fit parts together by tapered shafts and holes, with powerful hydraulic presses, as is done in the building of railway locomotives, marine engines, and similar machinery worked under heavy duty and subject to greater vibration? ELBRIDGE HEWES.  
Kewanee, Ill.

There is no question but that the use of press fits, as assembled by the method you refer to is called, could be widely employed in automobile building. To an extent it has been employed and unless our memory serves us ill a number of instances could be found in the automobile industry of flywheels forced onto crankshafts, gearwheels onto gearshafts, cams onto camshafts, etc. And certainly a method that proves satisfactory for holding locomotive driving wheels and railway vehicle wheels generally on their axles, not to speak of crankpins, driving-wheels, rims, etc., held by the same process, is not likely to fall down under the stresses of lesser magnitude involved in automobile service. Certain practical considerations must be borne in mind, nevertheless. Automobiles, though assembled in well-equipped factories, may have to be taken apart on the road or in ill-equipped repair shops, while press fits require facilities like those always available with the locomotive for their assembling. As the necessity for frequent or complete dismounting of automobiles continues to be reduced, we expect the press fits to become more widely recognized as good practice. In the meantime we will be pleased to publish any communications that go to show just what is being done in this direction at the present time by automobile builders in this country.

#### WHAT PARTICULAR SPRING WHEEL IS THIS?

Editor THE AUTOMOBILE:

[1,014.]—Will you kindly inform me of the construction, or the number of the U. S. patent, of the wheel invented in France that uses springs on the spokes instead of the inflated tire? In case you know the numbers of any other patents on this line, would be pleased to know them, so that I can send to the Patent Office for them. LOUIS BLESSING.  
Jackson, Mich.

Though you are doubtless unaware of it, you are asking far more than we could possibly give you. There have been scores, if not hundreds, of spring wheels brought out within the past few years in France and England, a few of which have actually been placed on the market and used in isolated instances. The same state of affairs prevails here with regard to the spring wheel, for ever since the early days of the bicycle there have been innumerable patents issued annually, so that probably the total number is well into the thousands by this time. If you have not access to a reference library in which a file of the *Patent Gazette* is to be found, ask any patent attorney to allow you the privilege of consulting his file. This publication is issued weekly by the Patent Office.

ASSASSINATION OF THE CANINE—BY AN EXPERT.

Editor THE AUTOMOBILE:

[1,015.]—The fourth question asked by Fred. D. Clark, of Prattsburg, N. Y., and answered by you in "Letters Interesting and Instructive" in your issue of November 21, interested me not a little, as during the past five or six years I have had considerable experience in running over dogs with my runabout, and not a few of these canines have been of the large variety. From the experience thus gained I would unhesitatingly answer the question as you did, and advise "preference for the immediate assassination of the dog, no matter how large, rather than try conclusions with any ditch, no matter how small."

In the practice of my profession, that of medicine, I have been employing continuously for over six years the same eight-horse power, single-cylinder runabout. Being of an early vintage, my machine is somewhat more noisy in operation than is the present style machine. As a result dogs seem especially to get ruffled up when I come along the highway, and run out at the automobile and bark and—get run over. Something over a year ago I was driving my machine along a dirt road on one side of which was a bank about three feet higher than the road. On the other side was a ditch. A large black dog, of a breed unknown to me, ran out of the yard and along the top of the bank barking at the automobile. From an adjoining yard a good-sized collie dog darted out and sprang upon the black dog. The result was that both dogs, clinched together, rolled down the bank and directly in front of my machine.

DR. COLTER AND HIS DOG—KING RUNABOUT

I had either to go over them or into the ditch, and I choose the former. I went over both dogs with both front and rear wheels on the left-hand side. The steering wheels were not in the least deflected, nor was there any bad jolt given to the machine. Strange to say, neither of the dogs was killed or even severely injured. They got up after being run over and ran off in different directions.

On another occasion I was driving along an asphalt street that was wet and very slippery. Suddenly, and without a warning bark, a very large St. Bernard dog ran out at the auto. When he was almost to the machine he braced himself and tried to stop, but the street being slippery his momentum carried him directly in front of the wheels, and over him I went with both front and rear wheels. As in the first instance mentioned, my car was not in the least deflected from its course by the contact with the dog, nor was the dog very badly hurt.

I have had the experience of running over a great many dogs, of all sizes and nationalities. I have never yet killed a dog outright by running over it. Some of them may have died later on as a result of injuries received. It is hard for me to explain this fact of freedom from mortality for the dog. It is certainly not because my machine is a light one. It will weigh over sixteen hundred pounds. I am enclosing you a picture of myself in this old machine. You will note that it is equipped with solid tires. This would seem to make it more than ever likely to deal out death to the unfortunate dog under its wheels, but such has not been the case.

The rather strange appearance of the tire on the rear wheel will need a word of explanation. It looks like a casing out of the clincher of the wheel. So it is, but the rear wheel has a solid tire on its rim, the same as the front ones. The outer casing was put over the solid rubber tire by way of experiment, in order to find out whether or not it would remove some of the jar or jolt in rough places. The outer casing used was an old one that had been damaged beyond repair, and it was held in position over the solid

tire by straps passed through holes cut in side of the casing and then over the wheel felloe. The particular casing shown in the picture has been on that wheel over eight months, and has never come off. The right-hand rear wheel has a similar casing on it, except that straps were not used to hold it in place. It was simply stretched over the solid tire, and it has stayed on the wheel as well as the left one with the straps. The vibration caused by the solid tires was lessened somewhat by these old outer casings used as described.

Cincinnati, Ohio.

L. S. COLTER.

ONE AUTOIST'S DETAILED EXPENSE ACCOUNT.

THE AUTOMOBILE: [Redacted]

[Redacted]

stated below. The year under consideration began September 1, 1906, and ended August 31, 1907, within which period the car was driven 8,545 miles, mainly in the business districts of San Francisco, but incidentally making tours to San Jose, Santa Cruz, Del Monte, and Lake Tahoe; the account shows as follows:

	Cost.	Cost in cents per car mile.
Tires: Casings .....	\$224.35	2.625
" Inner tubes .....	65.25	.764
" Repairs to casings and tubes.....	58.68	.687
" Anti-skid devices .....	36.00	.421
Power: Gasoline .....	221.50	2.592
" Oil and grease.....	41.26	.482
Ignition: Dry batteries and charging storage.	22.08	.258
" Spark plugs .....	18.00	.210
Repairs: Miscellaneous, ordinary.....	95.25	1.114
" Due to accidents.....	131.03	1.533
Lights: Carbide and coal oil.....	8.20	.096
Cleaning: Cotton waste.....	10.00	.117
" Garage clothing, chamois, sponges, etc.....	14.95	.175
" Sundry materials .....	7.95	.093
Miscellaneous: Garage rent.....	165.00	1.931
" Replacing lost and damaged tools .....	14.35	.166
" Sundry items .....	20.75	.243

The foregoing classed under main heads shows as follows:

	Total Cost.	Cents per Car Mile.
Tires, tubes, etc. ....	\$384.26	4.49
Power .....	262.76	3.08
Ignition .....	40.08	.47
Repairs .....	226.28	2.64
Lights .....	8.20	.09
Cleaning .....	32.90	.40
Sundries .....	200.10	2.34
Total .....	\$1,154.58	13.51

During the year 884 gallons of gasoline were used, costing from twenty to thirty-five cents per gallon and averaging out very nearly to twenty-five cents. The car miles per gallon were 9.666, some day's running on fair country roads showing as high as 16.63 miles per gallon, while other days in the city have shown as low as 8.82.

The foregoing accounts do not include attachments bought, i.e., top, speedometer, storage batteries, etc., costing in the aggregate \$317.93, nor anything for a chauffeur, whose wages alone would have doubled the total cost given and would have increased the car mile cost to above twenty-five cents. The car is in superb condition and of fine appearance, but the inevitable conclusion, in San Francisco at least, is that the motor car of to-day is not a poor man's vehicle.

B. N. C.

San Francisco, Cal.

HOW THE 20-30-HORSEPOWER RENAULT CHASSIS APPEARS AFTER BEING REFINED FOR 1908.

REGARDED externally only, it would require an expert to distinguish between the models produced by the Renault Frères for the 1908 season and those turned out of the Billancourt factory during the past year. This settling tendency, general throughout the automobile industry, is probably more pronounced in the Renault product than in any other of Europe or America; it is indeed a boast of the firm that between their smallest touring car and their most powerful racer there is no difference other than that of size.

Commencing with the small two-cylinder car used extensively in Europe or taxicab work and as a small town vehicle the series is a 10-14 four-cylinder, a 14-20, a 20-30 and a 35-45-horsepower car, all with four-cylinder engine. The only new model is a 50-60-horsepower six-cylinder chassis, built to meet a demand for a powerful and flexible automobile.

In the four models comprising the series of four-cylinder cars no changes have been made in general design, but a number of details have been perfected as suggested by experience. Except in the matter of suspension there is a uniformity of design throughout the series, the four-cylinder engine in each case being cast in pairs, thermo-siphon water circulation being adopted with plain tubular radiator behind the engine, thus giving the maximum of accessibility, and high-tension Simms-Bosch magneto as sole source of ignition supply. Transmission on all models is of the progressive type, giving four speeds forward and reverse, and drive is by propeller shaft to rear live axle. Three-quarter elliptic springs, adopted last year for the first time, are retained for all but the smallest models, on which the platform type is adopted. Shock absorbers on both front and rear springs are a standard equipment on all cars above 20 horsepower.

Some little change has been made on the gear box, the progressive type being retained, but the reverse clash gear being changed for a straight sliding type. In all other respects the gears remain as before, a feature of the Renault being that, although a progressive type, the arrangement is such that overall space is no greater than the majority of boxes on the selective principle.

Radiator design remains as on the 1907 models, but here again details have been perfected to allow of very easy dismounting and examination of the tubes. The base of the radiator fits into slots on the side frame and is held at each side by a single bolt, by the withdrawal of which and the inlet and outlet pipes the radiator can be removed as a unit. In this particular the maximum of simplicity appears to have been attained, there

being no pump and no other connection than the retaining bolts and the inlet and outlet piping from the cylinders.

Improvements in the lubrication of the engine comprise a device for regulating the amount of oil in the crank chamber and more accurately controlling the flow from the lubricator. An attachment, fixed at the right-hand side of the forward cylinder, provides for reducing or draining off entirely the amount of oil in the crankcase, shutting off the supply or turning it on; the device has the virtue of perfect accessibility.

In the six-cylinder model, produced this year for the first time, cylinders are cast in pairs, dimensions being 4.7 by 5.5 bore and stroke. Excepting a slight change in the carbureter, designed to give a richer charge for starting the engine, the six-cylinder model is a case of adding another unit, clutch, transmission, final drive and suspension being exactly as on the four-cylinder cars. Wheelbase has been increased several inches.

The real novelty of the season from the Renault factory is

FRONT VIEW, SHOWING ACCESSIBILITY OF ENGINE.

the production of a self-starter on all models. In reality they are two, the large cars being fitted with a device of the compressed air type, and the smaller ones with a purely mechanical arrangement allowing of starting the motor from the driver's seat. In all the four-cylinder models and on the six there is a small air pump compressing air into a tank and delivering it in correct sequence to the cylinders at what would be under ordinary circumstances the firing point. The pump, which is carried at the forward end of the motor and driven direct from the two-to-one shaft, has a single air-cooled cylinder with independent head. The method of attachment has been so simplified that by taking off a couple of nuts and withdrawing two bolts the cylinder head or the entire cylinder may be dismantled. Inlet and outlet valves are both in the cylinder head, the latter communicating by means of a by-pass with the metal tank attached to one of the side members of the frame. When a pressure of ninety pounds has been attained a membrane in the compression chamber is deformed to prevent the closing of the inlet valve on the compression stroke, the pump thus working free. The pump shaft is mounted on ball bearings.

About twenty liters of air are contained in the compressed air tank, this quantity being sufficient to start the largest four-cylinder model seven or eight times. Communication from the tank to the cylinders is through suitable piping connected up to a petcock on the dashboard and passing from there to a distributor above the engine. When the petcock, which is operated by a hand lever, is closed, no air can pass, and pressure is retained indefinitely in the tank. From the distributor mounted on the cylinders air is carried to each cylinder by independent leads, correct sequence being insured by a rotary distributing valve driven by an inclined spindle from the camshaft, and so set that air is admitted at what would ordinarily be the firing stroke. Ease of inspection of the automatic inlet valve in each cylinder has been assured by attaching the inlet pipe to the housing of each valve by means of a simple socket screw, a few turns of which will allow the pipe to be withdrawn vertically. The attachment of the distributor is of the same simple nature. For the six-cylinder motor the apparatus is the same with the exception that, instead of two openings at 90 degrees in the distributor, there are three at 120 degrees, admitting a charge of compressed air in the order 1, 5, 3, 6, 2, 4. Although the self starter is an extra, it has been specially designed to fit all 1908 models with the least encumbrance and in the most accessible manner.

On the smallest models the motor is started up from the driver's seat by an ingenious but simple mechanical contrivance, the operation of which consists in withdrawing the clutch, placing the gears at neutral point and pressing down a foot pedal similar to those used for clutch and brake, thereby giving an impulsion to the crankshaft. The starting pedal, mounted free on the same shaft as the clutch and brake pedals, carries a sector gearing with a rack mounted on the gear box and sliding within a bronze casing. By means of suitable gearing from a pinion driven off the rack, a free wheel, and a ratchet, the motor shaft is vigorously propelled on each depression of the starting pedal, full provision being made to prevent the effects of a backfire reaching the pedal, and this latter always being brought into position for starting up again by means of a spiral spring and guide. As with the compressed air starter, this device is fitted as an extra, but both the 10-14-horsepower four-cylinder car and the two-cylinder models are designed to receive it.

Considerable attention is now being paid by the Renault firm to the production of engines for motor boats and for electric generating plants, as well as the construction of light delivery vehicles. This year a couple of eight-cylinder engines have also been produced, both with the cylinders placed in V, one of them being of the air-cooled type designed to secure extreme lightness for aeronautical purposes, and the other being water-cooled and following more general Renault design.

## THE AUTOMOBILE CALENDAR. AMERICAN.

### Shows and Meetings.

- Dec. 9-14.....—Detroit, Riverview Park Auditorium, Detroit Automobile Dealers' Association. LeRoy Pelletier, manager.
- Dec. 14-21.....—St. Louis, Mo., Jal Alai Building, Second Annual Auto Show, St. Louis Automobile Manufacturers' and Dealers' Association. D. M. Strauss, manager.
- Dec. 28-Jan. 4...—New York City, Madison Square Garden, Importers' Salon. C. R. Mabley, manager.
- Jan. 14-18.....—Hartford, Conn., Foot Guard Hall, Hartford Automobile Dealers' Association.
- Feb. 1-8.....—Providence, State Armory, Automobile Show. Frank M. Prescott, manager.
- Feb. 10-15.....—Detroit, Light Guard Armory, Tri-State Automobile and Sporting Goods Association, Seventh Annual Show.
- Feb. 17-22.....—Cleveland, Central Armory, Annual Show, Cleveland Automobile Dealers' Association. George Collister, manager.
- Mar. 7-14.....—Boston, Mechanics' Building and Horticultural Hall, Boston Automobile Dealers' Association. Chester I. Campbell, manager, 5 Park Square.
- Mar. 9-14.....—Buffalo, Convention Hall, Sixth Annual Automobile Show, Automobile Club of Buffalo. Dal H. Lewis, manager.
- Mar. 21-28.....—Toronto, Canada, St. Lawrence Arena, Automobile Show. R. M. Jaffray, manager.
- Apr. 5-12.....—Montreal, Canada, Arena, Third Annual Automobile and Sportsman's Show. R. M. Jaffray, Mgr.

### Motor Boat Shows.

- Dec. 7-14.....—New York City, Grand Central Palace, National Association of Engine and Boat Manufacturers. Chester I. Campbell, manager, 5 Park Square, Boston.
- Jan. 1-8.....—Chicago, Coliseum, National Association of Engine and Boat Manufacturers. Chester I. Campbell, manager, 5 Park Square, Boston.
- Jan. 25-Feb. 1...—Boston, Mechanics' Building, National Association of Engine and Boat Manufacturers. Chester I. Campbell, manager, 5 Park Square, Boston.
- Feb. 3-8.....—Buffalo, Convention Hall, First Annual Power Boat and Sportsman's Show, auspices of Buffalo Launch Club. Dal H. Lewis, manager.
- Feb. 20-Mar. 7...—New York City, Madison Square Garden, Fourteenth Annual Motor Boat and Sportsman's Show.

## FOREIGN.

### Shows.

- Dec. 5-22.....—Berlin, Germany, Automobile Show.
- Dec. 21-Jan. 2...—Brussels, Show, Palace of the Cinquanteenaire.
- Jan. 18-Feb. 2, '08—Turin, Italy, Fifth International Automobile Exhibition, Palace of Fine Arts, Valentino Park, Automobile Club of Turin.
- Mar. 21-28.....—London, Agricultural Hall, Cordingley's Show.
- May 6-20.....—Moscow, Russia, International Automobile Exposition, Automobile Club of Moscow.

### Races, Hill-Climbs, Etc.

- April 1-13.....—Monaco Motor Boat Races and Motor Boat Exhibition, International Sporting Club of Monaco.
- April 25-June 25—Industrial Vehicle Competition, Automobile Club of France.
- May, 1908.....—Paris, Competition for Agricultural Automobiles, auspices of "L'Auto." (Exact date to be announced.)
- May 10.....—Sicily, Targa Florio, Automobile Club of Italy.
- June 1-18.....—Reliability Trials for Pleasure Cars, Automobile Club of Great Britain.
- June 9-17.....—Touring Competition for the Prince Henry of Prussia prize, Germany, Imperial Automobile Club of Germany.
- June 20-July 5...—Grand Prix, Dieppe Circuit, Automobile Club of France. (Exact date to be announced.)
- July 13-17.....—Ostend, Belgium, International Race Week, Automobile Club of Ostend.
- July 20-30.....—Ardennes Circuit Races and Coupe de Liedederke, Automobile Club of Belgium.
- August, 1908...—France, Coupe de la Presse, Automobile Club of France. (Exact date to be announced.)

STEARNS FOUR-CYLINDER MODEL, SHOWING CONTINUANCE OF MAIN FEATURES, BUT REFINEMENT OF MANY DETAILS.

FOR practically all the leading constructors of automobiles the 1908 season will stand out as the year of refinements. Main features of design have been fixed upon, tried out and proved so satisfactory that designers have wisely resolved to continue on the same broad lines, devoting all their attention to the perfection of details as suggested by experience.

The product of the F. B. Stearns Company, of Cleveland, O., is an excellent example of this line of development. There is nothing in the 1908 car which cannot be found on the model of the previous year, yet the work of refining is noticeable in every feature of the machine; to put it in other words, all distinctive features were fully decided upon for the 1907 models and the same features have been refined and improved for 1908.

Two models only are produced, a 30-horsepower four-cylinder and a 45-horsepower six-cylinder chassis, the two chassis being fitted with different bodies varying from a two-passenger run-about to a seven-passenger limousine. The four-cylinder car retains its predominating position, the six being built only in limited numbers, the Stearns people being of the opinion that this type of engine is valuable only where an excess of power is required above what can be safely produced from four cylinders.

Though given in the catalogue as of 30 horsepower, the four-cylinder engine with its cylinders cast in pairs probably would give on a brake test almost twice that amount, for its bore and stroke is 5 3-8 by 5 7-8. As on the previous models, the twin cylinders have aluminum heads and are mounted on a crankcase attached direct to the side frame. A feature of the engine arrangement is that the entire power plant, including the radiator, ignition, carbureter, lubricator and steering gear is mounted on the crankcase. Valve arrangement on the Stearns follows the now generally adopted practice of placing intake and exhaust on one side, the valves themselves being interchangeable, and employing a single camshaft, gears being inclosed by an aluminum housing. This arrangement leaves the right hand side of the engine free for the ignition system, which in this case consists of a high-tension Bosch magneto driven from the same shaft as the lubricator,

through inclosed gears. This is one of the few points in which last year's practice has been departed from. The high-tension plugs being placed on the same side of the motor as the magneto, a neat arrangement of encased wiring is possible between the two. Ignition by storage battery and a four-unit coil is also provided for, with separate plugs placed over the inlet valves.

Stearns has always been an upholder of ball bearings and on the new models uses them throughout not only the transmission but for the crankshaft, magneto-shaft, camshaft, pumpshaft and even the aluminum fan behind the cellular radiator. The well-known D. W. F. imported bearings are used exclusively. By reason of the numerous minor improvements carried out on each part of the engine a saving of no less than 300 pounds in weight has been effected on the chassis. The overall length of the motor, too, has been shortened, permitting its location three inches to the rear of the axle without increasing the wheelbase. Not only are the lines of the car improved by this disposition, but there is a better distribution of weight and a consequent economy in tires, but 3 1-2-inch tread being fitted on the lighter models. Engine control has been included in the improving process, spark and throttle levers now being placed above the

INTAKE SIDE OF FOUR-CYLINDER STEARNS MOTOR WITH 1908 IMPROVEMENTS.

SHOWING ACCESSIBILITY OF THE STEARNS DOUBLE IGNITION SYSTEM.

wheel, thus giving more knee room for the operator. Pedals are the same—clutch and brake, with accelerator pedal on the extreme right. Dashboard arrangement has also been simplified, the coil, pressure pump, manometer and auxiliary feed tank being all that is carried on the one-piece veneered mahogany dash, coil and tank casing being made to match same. One of the minor improvements is a toe switch, making it possible to switch over from storage batteries to magneto, or cut out altogether without changing position.

DISTINCTIVE STEERING GEAR.

The steering gear of the Stearns, which is of the worm and sector type, has as its distinctive features the use of ball bearings and the arrangement of the connection from the box to the knuckle. As will be seen from illustration, the drag link ascends instead of descends, as is usually the case, the connecting bar running forward close to the side frame, the transverse connecting rod of course being behind the front axle. Not only is ease of steering obtained, but all vital organs are well protected against road obstacles, the ensemble being one calculated to give entire confidence.

Transmission, as last year, is of the selective type, with final drive from countershaft to rear wheels by side chains. In the first of the organs transmitting power from the engine to road

wheels some changes have been made, the flat-faced band clutch being entirely disconnected from the brake mechanism, in accordance with best European practice. Considerable strengthening has been effected in the transmission, the gear box being attached to cross members and providing four speeds forward and reverse on the selective principle. Chrome-nickel steel is employed for shafts and gears and D. W. F. ball bearings are used throughout.

Semi-elliptic springs front and rear have been retained, but have been lengthened three inches in front and six inches in the rear, the back end of the rear springs being supported on dump irons. The channel-section pressed steel frame is dropped to lower the center of gravity without interfering with the road clearance and is narrowed in front to give a wider steering angle. Braking surface has been somewhat increased and the emergency brakes, operated by the side lever with cable connection, are equalized. The powerful,

metal-to-metal brakes on the countershaft have been provided with an improved method of adjusting, whereby the slack can be taken up in a few seconds and the bands securely locked. Fender construction has been somewhat improved and the lines slightly modified, with a view to completely protecting passengers from mud, no matter how fast the car is traveling or how dirty the road. The running and footboards are of cork linoleum, held by a brass molding instead of aluminum.

Body design for the coming season will comprise two full touring cars—a five-passenger standard car and a seven-passenger Pullman. In addition, a four-passenger roadster will be produced for those desiring a light, speedy car carrying this number of people. Limousine and landaulet, by the leading body makers of the country, will be supplied for the four-cylinder chassis when desired. A runabout body will be the standard equipment for the six-cylinder car.

In the six-cylinder model, nominally rated at 45 horsepower, but actually producing 90 horsepower on a brake test, all the distinctive features of the "four" are to be found. The same double ignition system is used, ball bearings are employed throughout and the carburetor is the regular multiple jet type, with a unique arrangement of inlet pipes. In transmission and drive the fours and the sixes are identical.

BRAKE ADJUSTMENT A FEATURE OF NEW STEARNS MODELS.

THE Touring Club de France has for its prime end the development of "le tourisme" in France in all its forms—on foot, à cheval, by carriage, automobile, railway or steamboat. Its badge is to-day as common throughout France as was the palmer's shell in the days of the Crusades, and is recognized by thousands, while the "delegates" of the club—to the number of something like three thousand—are found all over the country and are ever ready to help the traveler, gratis, with all manner of information concerning sights and scenes, roads and routes and hotels, etc., and to enroll new adherents.

Members are provided with a "carte d'identité," bearing a miniature photograph of the holder, and with the monthly magazine, *La Revue Mensuelle*. This publication contains valuable information for tourists of all ranks in France, and is made up of exceedingly ably written and illustrated articles on many subjects relating not only to touring, but with references to historic sights, local fêtes and celebrations and what not, and the whole is so put together that it is of great practical value and not as dry as dusty archæological reports or unattractive like a railway time table. The stranger tourist, none the less than the habitant of France, will hardly be able to get the maximum of comfort and satisfaction out of French travel without becoming a member of this most excellent institution.

The "annuaire," or hotel list, of the association is also a valuable aid to travel in the French provinces, and the club also publishes a series of specially designed and printed touring maps and plans which are marvels of the cartographer's art. There are now neighboring upon 120,000 members of this great and growing association, which itself is under the direct patronage of the President of the Republic, with M. Jacques Baliff as president of the club.

Of its great resources, 125,000 francs or more per year are set apart for the general refecton or repair of roads in unfrequented localities where perhaps the regular traffic would not stand this extra charge, as the railway managers say. Another fund provides for the placing of frequent landing stages for pleasure boats along the banks of the Seine and Marne and Oise and other navigable rivers, and for the posting of road signs up and down the length of very nearly all the routes nationales of France.

Within the parent body there is a special section known as the "Comité Technique," whose functions are purely advisory with regard to improvements in road-making, dust-laying, the installation of modern sanitary conveniences, etc. There is also a Comité de Protection des Sites et Monuments Pittoresques, a Comité Nautique, and even a Comité Hippique—for the horse, though rapidly giving up the ghost, is not wholly extinct as yet. Perhaps this committee will some day be supplanted by an-

T. C. F. SIGNPOST FOR WATERWAYS.

other devoted to the affairs of submarines, when these unstable craft shall have become the vogue of the world of sportsmen.

All this is something; it's a good deal, in fact; and when there is the added attraction of a magnificently equipped headquarters in Paris—on the Avenue de la Grande Armée, in the heart of the Parisian automobile world—the importance and value of becoming a member of this omnific association

will be apparent to everyone who is interested in pleasurable travel.

Besides all this, the automobilist may deposit the customs duty on his automobile on entering France with the club and get back the sum intact again on leaving, instead of having to go through annoying money transactions at the frontier or the port of debarkation. Of course, the thing has to be arranged beforehand, but the procedure is a simple one. The same facilities are offered to one who would take his automobile across the French frontier into Germany, Holland, Belgium, Italy or Switzerland.

**How Entrance to Foreign Countries Is Facilitated.**

All this machinery, with reference to the importation and exportation of automobiles in and out of France, is put into motion by a system which is built up in the form of a "triptyque." There's a "triptyque" by Rubens in Antwerp's cathedral, which is the best known to tourists in general, but this automobilist's "triptyque" is built on the same plan—a central panel, or leaf, and two outer or folding leaves, one on either side. To most automobilists this latter is likely to become as well known as that earlier and more artistic, if less practical, work of Rubens.

SLOW, DOWN GRADE

This automobile "triptyque" consists merely of three joined-together leaflets, one of which is given up on passing the customs house on entering, another on leaving, whilst the third, or last (endorsed by the officials of the customs house passed on leaving France), is held as a draw-back check, upon the surrender of which the original deposit will be paid over by the Touring Club de France—always provided that the formalities (which are not onerous) have been properly complied with at the respective Bureaux de Douane. Forms of application and further particulars may be had from the club direct.

Before the bubbles in the casserole which brewed the unsavory "Affaire Humbert" (that

MAIN ENTRANCE ON AVENUE DE LA GRANDE ARMÉE.

THIS FOR OUR COUNTRY INN, SAYS AUTHORITY T. C. F.

of the mythical millions) a few years ago had quieted down, the Touring Club de France, with the ready money right in its inside pocket, stepped in and bought of the liquidator of the affairs of "la Thérèse magnifique" her fine *hôtel privé* on Paris' Avenue de la Grande Armée, just beyond the Arc de Triomphe, and near the Porte Maillot entrance to the Bois.

A half a million quick cash was the price put upon the property by the administrator of the courts, and so the Touring Club de France came to be housed so magnificently. Previously its hundred thousand members had been catered to from a dingy apartment on the third and fourth floors of a nondescript structure in the Place de la Bourse.

To-day the Touring Club de France is as splendidly installed as any club or cercle in Paris, and all for practically a dollar a year, which is the cost to members. To be sure, this elegant

establishment at the gates of the Bois does not give you the opportunity of eating or drinking or playing cards within its walls, but still you may stalk majestically up its monumental *escalier* with an air of petty proprietorship if you will; you may consult its library of maps and guides — which the tourist will greatly appreciate, for there is no other collection, in Paris or out of it, so accessible or up-to-date; you may write your letters here, may

get full and free information on roads, routes, hotels, and even railway fares, and may attend conferences on such subjects as the "Deforestation of Mountains," "The Building and Upkeep of Good Roads," "Historic Pilgrimages," "Aeronautiques," and what not.

The scope of the club is very great, but it is by no means for tourists alone that it exists and does its great work; it is for all Frenchmen and all the world at large who have a care for historic and artistic souvenirs. If some historic or romantic shrine is in danger of being torn down or being made over into a gas works or something of the sort, the club, at the suggestion of its local delegate, comes forward and does a little organizing of public clamor and saves the day. This was the case with respect to that flower of the French Renaissance, the Chateau of Azay le Rideau, a few years since. The dastardly desecration which in this particular case came so near to being consummated, was no less than the possibility of this gem of a Touraine chateau being pulled down and transported block by block to the banks of the Allegheny or the shores of Puget Sound or some other equally inappropriate spot. Finally the French nation came to the rescue and bought it of its proprietors and proclaimed it a public *monument historique*, upon which vandal hands should never fall. And all this was brought about by the demarches made by the T. C. F.

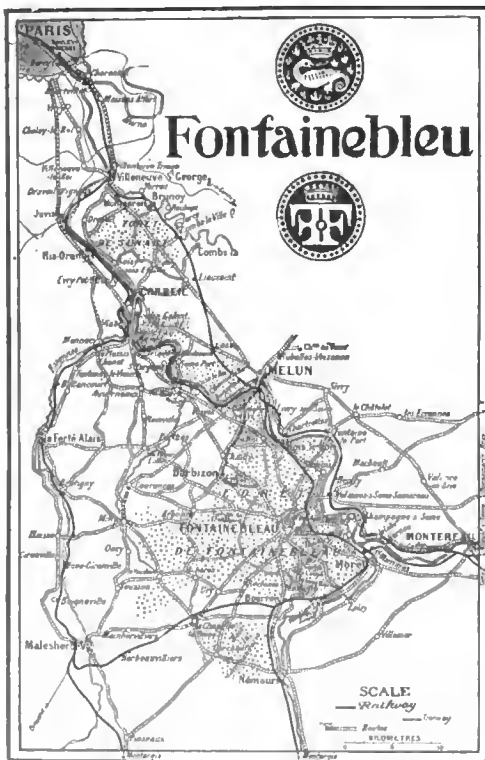

A CORNER OF THE WELL-STOCKED CLUB LIBRARY.

The Chateau de Josselin, in Bretagne, now the private residence of the de Rohans, was opened to visitors through the solicitation of the club. It is an ideal mediæval monument, every whit as grand as many in Touraine, and its doors and gates might ever have been closed to the public of all nations but for the solicitude of this great touring association.

If some great tree at Fontainebleau—standing on some historic spot—is to be felled, the T. C. F. comes forward again and the woodman's ax doesn't fall, nor is the stick of dynamite exploded which would blast open some narrow gorge of rock and bereave it of its picturesqueness. So, too, when it comes to modern improvements, the all-powerful society gets some eminent scientist or engineer to map out a project for a new bit of roadway, the restoration of an old bridge, or the erection of some memorial monument on a historic site. The Touring Club, usually, pays the bills, too, if not entire at least in part.

**Road Signs and Road Menders Receive Club's Care.**

The best system of road-signs ever planted above ground were thought out, produced and put into place through the energies of the club, and it has recently instituted a fund to buy waterproof clothing and rubber boots for the road-menders who do so much to keep French roads what they are. This is better than giving them a six-penny packet of stale tobacco and a pint of beer, as an analogous institution does in England. It costs more, to be sure, but it produces better results, and good roads are worth paying

PARIS TO FONTAINEBLEAU ROAD MAP.

for, as we are now just beginning to find out. What a pioneer Napoleon was, to be sure, and what an impetus he would give to automobilism if he lived to-day!

The *Tables d'Orientation* erected by the Touring Club at commanding viewpoints in France are a unique expression of initiative, and an admirable one. A *table d'orientation* shows a sort of circumferential birdseye view of everything roundabout, and is designed mathematically and topographically correct and reproduced in the form of a great circular enamelled table, and placed horizontally three or four feet above the ground. That recently erected at Cap Roux on the Riviera corniche is the latest of these innovations, but there are many others already in place, and many more projected, at various seacoast points, in the Pyrenees and in Dauphiné and Savoie. If some Rockefeller, Carnegie, or a Roosevelt wants to inaugurate a good idea in America, a land of magnificent birdseye views, let him endow a series of these admirable accessories. The accompanying plan will show how it is to be carried out in the most successful manner.

At still other commanding sites the Touring Club has erected benches (*with backs to them*), always facing some ravishing vista or a smiling prospect. The initials T. C. F. are deeply carved and

TO ENABLE THE WANDERER TO GET HIS BEARINGS.

blazoned thereon and there are hundreds of these all over France. There are no other amateur carvings thereon; the craze for writing or carving one's name, or that of their sweetheart, does not get a foothold here. The conveniences of the T. C. F. are apparently a public trust which is never betrayed.

The "*annuaire*," or hotel list, published by the club contains the names of many thousands of French hotels, with prices of the various accommodations offered. Sometimes, too, there is a special 5, 10 or 15 per cent. to be had in the way of a discount, freely given to members when their membership card is presented upon demanding one's bill. It is a real discount, too; there is no fake about it, with prices made out accordingly. These specially affiliated hotels are so marked in the "*annuaire*," which also, in addition to the name and population of the town, gives a note as to whether or no it is a telegraph or telephone office or a railway station, and whether there is a drugstore or not—in case you need it. It also indicates the hotels that have "running water" W. Cs. (this is really worth knowing), and as to whether there is a darkroom for kodakists—this, too, is worth knowing.

The *chambre hygiénique* instituted by the T. C. F., and now

THESE ARE T. C. F. IDEAL TOURISTS' BEDROOMS.

finding a place in so many French hotels, is simply a sane, sanitary sleeping-room, with iron or brass bedsteads, lacquered walls, tiled or waxed-wood floors, and a want of heavy draperies at the windows or woolly, mangy rugs on the floor. The craze for this sort of thing, replacing the stuffy sleeping-rooms of the French hotels of only a generation ago, is fast sweeping all over the country, as also the desire for the traveling automobilist to have a towel a little larger and thicker than a handkerchief and a wash basin something larger than a coffee cup. These things as well are changing for the better. Again the T. C. F.! This amelioration of the French country hotel has been one of the greatest triumphs of the club, for it is to its initiative that it has been due.

As a member of this great Touring Club you are furnished with a little pamphlet of blank forms, which you are expected to fill up from time to time as you find a hotel well or ill appointed, and with this information at hand the editor of next year's "*annuaire*" will be able to keep his list up to date. When it is stated that this desired information comprehends such details as the following, its great value will be readily appreciated: Cleanliness and lighting of sleeping-rooms; quality and abundance of the table; general aspect of the hotel and its appointments; nature of its clientèle; general impressions of the landlord and the personnel; is the hotel provided with detailed maps of the region? are there means for the proper care, storage and repairs of automobiles? is there a darkroom? etc. In addition to this you are asked to give comments on the outlook and accessibility of the house and the length of your stay.

MAIN STAIRCASE IS NOT LACKING IN ELEGANCE

From all this is boiled down certain pertinent facts that are of inestimable value to travelers. This is real, valuable coöperation such as does credit to the brotherhood of stranger automobile nomads, now more numerous in France than in any other country on the globe. This is because the French know how to cater to travelers of this class without boring you stiff by overdoing the thing, and without overcharging for the accommodations offered. There is a written or unwritten law in France which frowns down any radical overcharging, though not many seem to know this. It takes time to get satisfaction, if you think you are being held up in some hotel or garage, and in many cases the thing will not be worth following up. But there is that pretty generally recognized law, nevertheless, which prohibits "unfair trading," and its platform is a pretty broad one.

Another new idea of the Touring Club is the installation of country inns, or châteaux, or auberges in likely places, where, perhaps, the local traffic would not support a more pretentious establishment. This will probably lead to the birth of many incipient resorts, but what matter, the traveler of to-day expects to find accommodation for himself and his modern beast of burden, the automobile, wherever he chooses to cut off the gas.

The club will furnish any prospective *aubergiste* plans and particulars as to how he may install a modest inn and will even make arrangements whereby he may get his material at inside figures. This, too, is an idea worthy of great development. The diagram herewith gives an idea of the simplicity and convenience of the small hotel known as the *Auberge du Touring Club*. It's worth being tried in America. Heaven knows, some of our "road-houses" are awful enough, and infrequent enough, too. The idea is susceptible of being worked up into something very important and run on the same grandly organized scale as Pullman cars are run on the railways. Here's a chance for the capitalist looking for a new industry to exploit.

Now for a few facts of practical information. To become a member of the Touring Club de France fill in the application form and forward it to M. le President du Touring Club de

France, 65 Avenue de la Grande Armée, Paris, with a sum equal to six francs (say a dollar and a quarter) in the form of an international money order or an American Express Company's "foreign cheque." It's worth the doing, at any rate, whether one actually makes use of all the facilities offered or not. When wanted, the able services of this grand institution, to be had practically for nothing, will be worth all the trouble that has been taken to acquire the right to them.

An arrangement in existence between the American Automobile Association, which has the headquarters for its national secretary, F. H. Elliott, at 437 Fifth avenue, New York City, and the Touring Club makes it possible for members of that association to secure immediate membership upon presentation of their tickets at the Paris offices of the Touring Club. The same results can be obtained by mail by inclosing with the application blank the A. A. A. ticket, which, of course, is returned with the Touring Club ticket. Membership in the American organization is recognized as a sufficient introduction for immediate attention by the French body. In like manner the Touring Club members who visit America are accepted by the A. A. A., though it must be admitted that few Europeans have elected to tour extensively in the United States, which is just beginning to really awaken in the matter of roads building.

### SEVEN MODEL HIGHWAYS INTO CITY OF PARIS.

PARIS, Dec. 2.—Although the roads of France are so uniformly good as to earn universal commendation, the outlets from Paris are, without exception, in a poor condition. M. Barthou, minister of public works, has just declared in an official communication to M. Ballif, president of the Touring Club, and M. Chaix, of the Touring Board of the A. C. F., that during the next ten years all the main roads out of the capital will be entirely reconstructed on improved principles. It is intended to lay out seven main roads, paved with small cobblestones on a bed of cement, thus providing easy access to the city from any point of the compass.

## 2,152,000 MILES OF PUBLIC ROAD—7.14 PER CENT. IMPROVED

WASHINGTON, D. C., Dec. 9.—Some interesting facts and figures regarding the road question in this country are contained in the eleventh annual report of the Secretary of Agriculture, recently submitted to President Roosevelt. As the question is one of absorbing interest to automobilists throughout the country, the following excerpts from the report are not without interest:

The close of the year marked the completion of the first census ever made to determine the road mileage, revenues and expenditures in this country. This investigation was begun early in 1905. Information covering the calendar year 1904 was obtained from carefully selected correspondents in every county in the United States, from State Highway Departments, State geologists, city and county officials, employees of the Office of Public Roads on field duty, commercial and agricultural associations, and newspapers—in fact, every possible source of information was used. The bulletin recently issued on the subject shows the enormous total of nearly 2,152,000 miles of public road; that 7.14 per cent. of this mileage has been improved, and that the total expenditures for 1904 were approximately \$30,000,000. Considering the fact that our improved roads have been in process of construction for a number of years, it becomes evident that the results which we are obtaining are totally inadequate to the amount of money expended, and that the mileage is so great that we must of necessity classify our roads according to their importance, bearing in mind the fact that by far the largest proportion of our earth roads must be maintained as such for many years to come.

The construction of object-lesson roads in co-operation with local authorities was continued during the year along the same lines as in previous years, excepting that greater attention was given to the building of earth, sand-clay, and gravel roads.

The trend of public opinion with reference to our public roads is indicated by the requests which have been received during the past

year for the detail of men to lecture on road improvements. In former years the demand for lectures on road improvement came largely from road organizations, but during the past year requests have been received from agricultural, industrial, scientific, and commercial organizations which are taking up the subject.

In recent years perhaps the most important, and certainly the most difficult, problem which has engaged the attention of highway engineers is the prevention of dust. Until the general introduction of automobiles, dust was considered as neither more nor less than a nuisance. The problem has now, however, assumed a more serious aspect. The existence of our macadam roads depends upon the retention of the rock dust formed by the wearing of the surface. Under ordinary traffic conditions this dust remains on the road and consolidates to form a fresh wearing surface. But a heavy rubber-tired automobile moving at a high rate of speed produces a partial vacuum behind each wheel which sucks up the dust from the road surface and throws it into the air, to be carried off by the wind. This action soon strips the macadam road of all fine material, the result being that it soon disintegrates.

France, both by reason of her mileage of macadam roads and the general use of automobiles, has given this subject the earliest and most thorough consideration. Investigations and experiments have also been conducted in England, and to some extent in this country. During the past year a thorough investigation was made of the systems in use both in France and in England. Experiments with tar and oil were conducted during the past summer in Kentucky and Massachusetts with a number of materials and preparations designed to preserve macadam road surfaces.

This is a subject which should engage the earnest attention of the National Government at once. No matter how important we may deem the building of good roads, we cannot but consider it even more important to preserve those which have already been constructed. Investigations of dust preventives and road preservatives will be conducted by the Office of Public Roads during this and the next fiscal year as far as its facilities will permit.

## EARLY WINTER DOINGS OF THE AUTO CLUBS

### SIGNBOARDING BY LIVE MASSACHUSETTS CLUB.

SPRINGFIELD, MASS., Dec. 9.—The extensive mileage of excellent highways radiating from Springfield is now being posted with cautionary signs on all dangerous points, under the auspices of the Automobile Club of Springfield, with signs furnished by the Massachusetts State Automobile Association. One hundred signs have been furnished the club for this purpose under the terms of a special offer made to the clubs by the State organization, and the Springfield club is the first to avail itself of the offer and to actively undertake the work.

The signs are made of enameled tin with "Drive Carefully—Sound Horn" in white display letters on a blue background. The club guarantees to furnish a durable mount for the signs where they are in plain sight of passing tourists, and also furnishes the State organization with a catalog of the exact locations. The signs will be posted on roads from this city to Huntington, Northampton, Palmer, and State Line, and another 100 to be received later will be posted on less frequented roads. The signs will be placed both sides of curves, hills, and underpasses, where accidents are likely to occur from careless driving or ignorance of local highway conditions.

### TOLEDOANS PROMOTE AN AUTOMOBILE CLUB.

TOLEDO, O., Dec. 9.—Plans for the organization of the Automobile Club of Toledo were formulated at a dinner given at the Toledo club recently by Edward D. Libbey. Mr. Libbey invited a number of well-known autoists resident in this city, and the members of the club to be were addressed by President F. T. Sholes, of the Ohio State Automobile Association, and President E. S. George, of the Detroit Automobile Club, both of the speakers outlining the advantages to be gained by organizing. A committee consisting of E. J. Marshall, A. L. Spitzer, George S. Mills, Marshall Sheppey, and J. M. Steenberg, was appointed to draft a constitution and by-laws and to arrange for the incorporation of the club. Next spring, it is the intention of the newly formed club to have several of its members appointed as special policemen to aid in the suppression of illegal speeding. E. D. Libbey was appointed temporary chairman of the organization, pending incorporation, and G. S. Mills, secretary *pro tem*.

### SOCIAL FEATURES OF THE A. C. OF AMERICA.

NEW YORK, Dec. 10.—Next Tuesday will be ladies' day at the Automobile Club of America, on which occasion tea will be served from 4 to 6, and music provided. The regular Tuesday evening club dinner will be held the same day, at 7:30 instead of 6:30, as heretofore, and will be followed by an illustrated lecture by O. P. Austin, chief of the Bureau of Statistics, Department of Commerce and Labor, Washington, D. C., on "Queer Methods of Travel in Curious Corners of the World." Announcement is made that the annual banquet will be held in the Assembly room of the clubhouse, Saturday, January 25, 1908.

### CHAIRMAN HOWER TO HEAD A. C. OF BUFFALO.

BUFFALO, N. Y., Dec. 9.—The annual meeting and election of officers of the Automobile Club of Buffalo will take place at the club headquarters on next Monday evening, December 16. The nominees are as follows: For president, Frank B. Hower, chairman of the Touring Board of the American Automobile Association; vice-president, John M. Satterfield; treasurer, Laurens Enos; secretary, Dai H. Lewis. The members proposed for the new board of directors are Edward H. Butler, Edward R. Thomas, Charles Clifton, James N. Beyers and George C. Diehl. The total membership of the club is now 1,127.

### QUAKER CITY MOTOR CLUB MAY HAVE A HOME.

PHILADELPHIA, PA., Dec. 9.—If the enthusiasm manifested at last Thursday night's meeting of the Quaker City Motor Club is a criterion, that organization will have a home of its own before many moons. The membership has been growing by leaps and bounds recently, until the cozy but small quarters in the Hotel Majestic have become much too restricted for comfort. Especially on meeting nights has the lack of room been felt. Besides, the Majestic is too far away from the fumes of "Gasoline Row" to be an ideal home for the club, despite its many comforts. When, therefore, a proposal was laid before the club whereby a whole building in the neighborhood of Broad and Walnut streets was offered at a rental very little, if any, in excess of what is paid now, the members took hold with avidity. The building in question has been used as a club for several years, and but very little money need be spent to adapt it to the needs of the growing membership list of the Quakers.

If the proposed deal materializes—and it is almost certain that it will—a café will be installed, in charge of a well-known caterer, and all the requisites of an up-to-date club put in. Later a swimming pool may be added to the attractions of the new home. Final action on the matter will probably be taken at the January meeting and a special committee appointed.

Five cars, carrying a score of passengers, made up of officials, newspaper men and photographers, took a two-day jaunt, last Saturday and Sunday, over the route of the Quaker City Motor Club's endurance run, which is scheduled for January 1 and 2 next. Besides "spying out the land" preparatory to the adoption of a schedule, Chairman E. C. Johnson, of the club's contest committee, made hotel and garage arrangements at Allentown, where the run will stop over night, and selected points along the route where checkers will be located.

The first day's run, to Allentown, via Doylestown, Easton, and Nazareth, is about 79 miles, while the return route, via Kutztown and Reading, is a trifle longer. A technical committee of three will examine all of the cars after their return, and in the event of ties, the machines which are in the best condition will be awarded the cups in their respective classes.

### DOINGS OF THE CLUB AT WORCESTER, MASS.

WORCESTER, MASS., Dec. 9.—The Worcester Automobile Club will have its second smoke talk of this season to-morrow night. Alfred Thomas will tell of his 3,500-mile tour of Europe last summer in his Pierce car.

J. J. Quinn has returned from a trip to Great Britain and France. While in Paris he attended the Salon and comes back to Worcester with praises for the Salon, but his preference for American cars stronger than ever.

M. P. Whittall, of the Worcester club, has been deprived of his license rights for a term ending March 27, 1908. This was on the initiative of the Massachusetts Safe Roads Association, and the State Highway Commission suspended the license. Mr. Whittall was driving a car which struck a child in Worcester last summer and the action by the association was taken while there is a civil suit pending against him brought by the parents of the child.

### EDWARDS NOW AT LONG ISLAND CLUB'S WHEEL.

BROOKLYN, N. Y., Dec. 9.—The Long Island Automobile Club has elected these officers for the coming year: President, Charles Jerome Edwards; vice-president, C. B. Barker; secretary, Russell A. Field; treasurer, Louis T. Weiss. Governors for two years, William Payson Richardson, Dr. T. H. Sharpe, and J. H. Emanuel; membership committee, Samuel F. Burns and F. G. Jahn.

What Will Another Year Bring Forth in Shows?

It is with a sigh of relief that the automobile manufacturer, dealer, and everyone down through the long list of those whom shows affect more or less directly, view the closing of the "big show" season. There are still two events of some importance: the Importers' Salon in Madison Square Garden and the Boston show in March, to take place before the season can finally be said to wind up. But the first holds no great interest for the American industry, while the second is something for which the dealer is largely responsible, and next March is still somewhat in the future. Looking back on what has taken place during the past two months, it would seem as if this first trial of early show dates can definitely be put down as the last, at least under similar conditions, and by this is not meant times of financial depression, as they were something that could not be foreseen.

The first New York show felt the full brunt of this unfortunate period, while the second exhibition happily occurred at a time when it did a great deal of good, but neither succeeded in demonstrating the necessity or expediency of holding shows so far in advance of the dates that have come to be regarded as more or less fixed in this country. The maker could have profited by early show dates in past years when new models were made ready just in time for exhibition and deliveries did not begin until a month or two later, but that time is long since past and conditions have undergone a complete change in the interim. What the next year will bring forth in the way of a show situ-

ation is somewhat problematical at the moment, though it seems safe to predict, even now, that there will be some radical changes both in dates as well as other important features, not the least of which concern the sponsors of the different shows.

It is definitely understood that the A. M. C. M. A. and the M. and A. M. will promote an affair entirely of their own planning in New York, and the Chicago show has assumed such proportions that a split is anticipated there also. It is to be presumed that the Licensed interests will continue the even tenor of their way in both cities, where shows are concerned, though there is more or less talk of an open-air event on novel lines.

Why So Difficult to Evolve Sensible Rules?

One of the strangest anomalies in connection with automobile contests of almost every nature included in the long category of events of past years, is to be found in the fact that rules, which should at once be sensible and practical, have been found almost impossible of attainment. Lack of experience could easily be cited as the cause in earlier days, but, as an excuse, this should have lost most of its potency by now. The new attitude assumed toward road racing by British interests furnishes two striking examples—the first, a commendable one that could have been adopted at the outset with equal facility, and the second, a hopeless right-about-face movement that can only serve to further delay the adoption of common-sense standards.

The former of these is the new Tourist Trophy, which will henceforth be a road race, pure and simple, and in which a low maximum weight limit formerly produced such absurdities as papier maché bonnets, perforated frames, and, in short, anything but touring cars. Instead, there is now to be a maximum cylinder bore and a minimum weight limit. But in the new 2,000-mile reliability trial, everything has been subordinated to time of performance, this term being held to cover even such details as replenishing fuel tanks. Hair-splitting niceties are ridiculous, as we have had occasion to note very recently, but sweeping them away with one hand and putting them on with the other does not provide the solution desired. Club committees generally have proved themselves woefully incompetent in this respect, and, sad to relate, only an occasional gleam of encouragement shows that better things may come in the fullness of time. A National Committee, like the new Technical Board of the A. A. A., should, and probably will, provide rules for standard kinds of technical contests.

Enforcing Blue Laws Was Physically Beneficial.

It may have been a mere coincidence, but it was plainly evident to any observer that on the first day Commissioner Bingham put into force the regulations designed to give New Yorkers a greater respect for the sanctity of the Sabbath the weekly automobile parade should have more participants than usual. Riverside Drive, Broadway and Central Park, from the breakfast hour till sunset, were much more animated than usual with every class of machine from a noisy single cylinder carrying a full load of passengers—the rule appears to be that the smaller the machine the greater the number of people to be crowded into it—to the handsome limousine with liveried men on the front seat. But the majority of those taking the air in this fashion were people owning moderate-powered cars, and who were out for the pleasure of the outing, the owner in nearly every case being at the wheel. The supporters of the new city regulations would probably be surprised to find themselves joined by automobilists in the cry for the "lid down," for so long as weather conditions are satisfactory few of those who opened the garage door when the theater door had been bolted will object to a continuance of the experiment. But the powers-that-be might have care for the hereafter of the taxicab man and suggest more bolting down—then there would be another story to tell.

## A. A. A. AND AUTO MAKERS WILL WORK FOR COMMON GOOD

THE first meeting of the new executive committee of the American Automobile Association was held in the First Regiment Armory, Chicago, December 6, a majority of the board comprising seventeen members being present.

President Hotchkiss presented a report concerning the policies and plans of the association for the ensuing year, which was unanimously adopted.

Reports were received from the chairmen of the various boards, including an announcement from the Vanderbilt Cup Commission, stating that at a meeting held in New York, November 27, it was definitely decided to hold the Vanderbilt Cup race in the fall of 1908, and that the time, place and conditions for this contest would be announced as soon as possible.

The recommendations contained in a communication from Chairman Terry, of the Legislative Board, suggesting that the automobile manufacturing associations, through their members, enlist the support of the Federal bill by their agents throughout the United States, and the outline of a publicity campaign through the manufacturing organizations, were approved.

President Hotchkiss, as chairman of the Special Committee on Sanctions, recently appointed by the association to take into consideration the motor racing situation as intensified by the large number of accidents to spectators and participants during the past year, reported that this committee, at a meeting held on December 5, adopted the recommendations which had tentatively been agreed upon at a previous meeting held in New York, and it was stated that the restrictions and recommendations had been unanimously approved by the representatives of the several automobile manufacturing organizations, and that the association would be supported by the manufacturers of the country in their enforcement.

President Hotchkiss also reported on behalf of the Central Conference Committee that the association had received assurances from the various bodies represented on such committee that it would be supported to the limit in the enforcement of the sanctioning power as to all classes of automobile contests, also that at such conference a working basis was arrived at between the various associations interested in and working for desirable automobile legislation and the furtherance of the good roads movement in the State and nation.

The chairmen of the racing and technical boards were instructed to investigate and report at a meeting of the executive committee of the American Automobile Association to be held early in January as to whether the association should hold under its own auspices a stock chassis touring car contest in the spring of 1908, and if such contest seems desirable to suggest the time, place and conditions thereof.

A resolution was unanimously adopted directing that the national boards at once take under consideration the advisability of holding a great national convention of the association at some convenient point during the summer of 1908.

In addition to a considerable number of individual members, the following organizations were elected to membership: Savannah Automobile Club, Savannah, Ga.; Automobile Club of Hawaii; California State Automobile Association.

### Contained in President Hotchkiss' Plans.

**IN GENERAL.**—A continuance of the general policy previously followed, including a progressive increase in membership and a substantial increase in the work and functions of the various national boards.

To that end, (a) the adoption of a plan whereby the individual membership of the association in all of the States will be much increased; (b) the organization of additional clubs in all cities of more than 10,000 population, and the federation of such clubs into State associations, where the latter do not now exist;

Also, the stimulation from national headquarters of (a) club activities, through correspondence and ample publicity touching the work of the national body, as well as through monthly printed

bulletins issued by the clubs, frequent meetings, and carefully conducted campaigns looking to new members; and (b) State association work, not merely by correspondence, but by visitation and suggestion.

**MEETINGS.**—As an example in service, regular monthly meetings of the board of directors, or its executive committee, held, perhaps, in different parts of the country and attended, if possible—at least, executive committee meetings—by a majority of the members;

Also, frequent and regular meetings of the various boards, or, in case this is impracticable, of their executive committees, thus enlisting the services of many men and not placing reliance entirely on the enthusiasm or sacrifice of one;

Also, a national convention of the association, with particular reference to legislation and good roads, at some central point, during the summer season.

**BOARDS.**—Real activity by each board; co-operation and consultation between boards whose functions in any way overlap; as, for instance, those of the racing and technical boards; vice-chairmen and secretaries in each of the boards seeming to require them.

In legislation, a continuance of present agitation looking toward the adoption of a federal registration bill, and, if possible, sufficient demand and pressure to secure the passage of such bill at the present session of the sixtieth Congress; also, and more important, active co-operation between the legislative board and the corresponding committees in the various States whose legislatures meet in 1908, to the end that in several of them the association's proposed uniform motor vehicle bill will become a law ere the touring season begins.

In touring, increased activity both in the touring board and in the corresponding committees of the State associations and clubs, looking to the aggregation and analysis of touring information available to all members, without charge, on application to the secretary of the association or the chairman of the touring board; also, a plan whereby, in those sections of the country where trunk touring routes are found, there shall be a geographical distribution of road sign work among the clubs in such territory, to the end that all such roads will be marked by signs, bearing the emblem of the association, and clearly indicating directions and distances; and—but of lesser importance—the conduct of the association's annual tour in 1908, perhaps, from some central point and in conjunction with the national convention, previously mentioned, instead of across the country from one center to another.

**SANCTIONS.**—Sanctions to be granted only by the racing and technical boards, on application made through national headquarters, to club or State association members only, on payment of ample fees—the amount to be regulated by (a) whether for national or international contests, and (b) for contests of minor importance—on an agreement on the part of the applicant, made in the application, to strictly observe the rules of the board granting the sanction, and the terms thereof; penalties and disqualifications to be promptly and rigorously administered.

In short, sanction, supervision and responsibility, or neither; no promoters, other than clubs or State associations; no graft.

**MANUFACTURERS.**—Hearty co-operation between the association and its contest boards, on the one hand, and the national associations of manufacturers, on the other, both to prevent a multiplicity of contests, and to make the results reliable and valuable.

**THE PRESS.**—Co-operation with all publicity agencies, by furnishing not merely news announcements as to the activities of the association and its boards, but, all proper information as to the management, policies and finances of the association; and, in return from the press, assistance in preventing publicity concerning fake promotions, uncertain contests, or unsanctioned events.

**FINANCES.**—A rigorous insistence on the part of the national body that the State associations and clubs perform their financial obligations to the association; sanction and entrance fees and advertising rates sufficiently large to make the racing, technical, touring and publications boards at least self-sustaining; and a complete revision of the fiscal policy of the association before the end of the present fiscal year.

I am not such an idealist as to believe that all of these things can be accomplished, or that even a part of them can be done without some friction and, perhaps, criticism. It may be safely said, however, that, with some such outline of policy before them, the enthusiastic members who now form the executive body and captain the various boards may be able the better to work together for the perfection and efficiency of the association, the maintenance of its prestige and the ultimate achievement of, at least, some of the ideals of the present executive.

WILLIAM H. HOTCHKISS,  
President.

December 6, 1907.

## BRIEF ITEMS OF NEWS AND TRADE MISCELLANY

### NEWS AND TRADE MENTION.

If the proposed automobile race from New York to Paris is carried out, according to plans now being discussed, the H. H. Franklin Company declares that one of their air-cooled cars will be entered.

Manager Gaston Plaintiff, of the Ford Motor Company, is enthusiastic over the results obtained by his company with delinquent accounts which have been placed in the hands of the collection department of the New York Automobile Trade Association.

Announcement is made from Syracuse that a novel town vehicle has been added to the Franklin line. The new model is fitted with a brougham body on the chassis of the Model G 16-horse-power runabout, and will have inside steering. Wheelbase being only 92 inches, the new model can be easily handled in narrow and crowded thoroughfares. Total weight is only 1,700 pounds.

Announcement is made by Paul La-croix, general manager of the Renault Frères Selling Branch, that it has been decided to open new branches for the sale of Renault cars in various cities in the United States. For Chicago and San Francisco arrangements have already been completed for the immediate opening of branch houses. As an indication of the growth of the Renault firm, it is declared that in 1898 six cars were produced by six workmen, in a plant covering 27,000 square feet; for 1908 orders have been booked for 4,600 cars, workmen number 2,600, and the works cover an area of 450,000 square feet.

"Don't run your car to the limit of its power," says M. B. Hatch, sales manager of the Thomas. "Any car, one, two, four or six cylinders, will run better and longer if its power is not taxed to its utmost. An example of this was recently shown when one of our older models was brought to the factory for overhauling. Although the car had been run many thousands of miles, the entire mechanism of the car was found to be in perfect condition. When complimented on his driving, the chauffeur said: 'It's easy; I take the steep hills on third speed.' The Thomas Company early recognized the truth of this, and were the first in America to use four speeds forward. It is not that the car can't take the steep hills on direct drive, but a driver will use the Thomas third speed when he will not use the intermediate of cars provided with a three-speed transmission."

"Some people cannot get out of doing things from force of habit, it seems," says the Binghamton (N. Y.) *Herald*. "This morning a man riding in one of those fussy little gasoline motor runabouts that hold two people 'fussed' into Collier street and stopped his 'fussy' at the curb alongside the Court House green. Then he uncovered his legs by taking off a heavy fur robe, and threw the robe over the business end of the car in front. Now, maybe that man had been in the habit of driving a horse, and being careful of his beast in cold weather, always covered him with the robe whenever he

stopped. The bonnet being in the front like a horse, perhaps the man thought he would carry out his plan of being kind to his mode of propulsion. Bystanders looked on, expecting him to pat the bonnet on the 'nose' or take out a weight and strap and 'hitch' the car to a telegraph pole or do something else." Phillip Bellows, secretary of the Aluminum Solder and Refining Company, Oswego, N. Y., who was amused at the above, thought it would be an act of charity to call the editor's attention to the fact that water freezes in winter.

The Swinehart Clincher Tire and Rubber Company, of Akron, O., has issued a notice of the Auto Truck Owners' Amalgamated Association comprising the following resolutions: (1) That they will employ only chauffeurs who will exercise good judgment in the handling of their auto trucks. (2) Realizing that truck owners are liable for heavy damages on account of trucks side sluing, striking other vehicles and endangering life and property, they have decided that they will only buy tires corrugated on the tread, provided with a central groove in which a hardened chain can be placed, when conditions demand its use. (3) That they will exercise due care in selecting chauffeurs who know the difference between a good tire and a poor one.

Among the principal exhibits of commercial motor cars at the second annual automobile show of the Dealers' Association of St. Louis, December 14 to 21, will be that of the Logan Construction Company, of Chillicothe, Ohio, which will show a full line of its 1908 product. The exhibit will occupy one of the principal spaces on the main floor and will be made by the company in conjunction with its distributors for Missouri, the Logan Motor Despatch of St. Louis. One of the biggest single shipments of commercial cars ever made in this country will be made at the same time by the Logan company, consisting of fourteen four-cylinder delivery wagons, for the use of the St. Louis *Post Despatch*, which will inaugurate motor delivery throughout the city and its suburbs. The shipment of a train load of commercial trucks to a single company is something unique in the history of the business and will attract wide attention. It proves conclusively the rapidity with which the motor truck business is increasing, and the experience of the *Post Despatch* with motor delivery will no doubt be watched with close attention by all the other big newspapers of the country. The cars are the regular Model "R" delivery wagons, equipped with a 20-horse-power four-cylinder, air-cooled motor, and with a capacity of 1,500 pounds paying load.

### NEW AGENCIES ESTABLISHED.

The Dupont Garage Company, 2020 M street, N. W., Washington, D. C., agents for the Columbia and Corbin cars, has taken up the Lozier line for the District of Columbia.

Owing to increasing business, the National Battery Company has taken possession of the entire building at 236 West Fifty-fourth street, New York, one

door west of Broadway. Floor space has been trebled by the change.

The Harrington Garage Company, at Worcester, Mass., has taken over the premises formerly occupied by the Harrington Auto Station, now defunct, and will undertake extensive alterations with a view to increased business. G. H. Phelps, former agent for the Corbin automobile in Worcester County, and F. L. Stanford, are the proprietors.

### PERSONAL TRADE MENTION.

E. R. Benson, for some years prominently connected with the Hartford Rubber Works Company, and lately secretary of that concern, has resigned to accept an important position in the sales department of the Cadillac Motor Car Company, Detroit.

From the first day of January, E. Ralph Estep will devote himself exclusively to the Packard Motor Car Company, having accepted the position of advertising manager. From Chicago, where Mr. Estep has plied his facile pen for the past few months in successful publicity efforts for the Detroit firm, a move will be made to factory headquarters.

### NEW TRADE PUBLICATIONS.

The car that has no valves has its virtues extolled in the 1908 catalogue of the Elmore Manufacturing Company, Clyde, O. The three models for the coming season are presented in full page illustrations and numerous arguments advanced to prove the two-cycle superiority over the four.

What the manufacturers think of the Richmond car, what makers say of it, and how it should be kept and maintained, is told in the catalogue received from the Wayne Works, Richmond, Ind., where the Richmond car is constructed. Three models are produced, all with four-cylinder air-cooled engines.

United under the same outside wrapper, a couple of elegant booklets have been sent forth from the Electric Vehicle Company's publicity department, at Hartford, Conn., one dealing with gasoline and the other with electric cars. Both are excellent examples of the typographical art, and are further enhanced in value by a colored frontispiece signed by Wildhack.

Eighteen models, from a small four-cylinder town vehicle to a six-cylinder car with limousine body, are included in the large and handsomely produced catalogue of the E. R. Thomas Company, Buffalo, New York. The big series includes, in addition to the output of the Buffalo factory, all the models of the Thomas-Detroit concern, the two being marketed together.

In a sixteen-page illustrated catalogue the George N. Pierce Company presents its models for next season, showing the two six-cylinder models, and the four complete and in detail. Main lines of construction and detail improvements are described and illustrated, and the booklet is embellished by a number of excellent colored engravings of the firm's touring and inclosed cars.

# THE AUTOMOBILE

VOL. XVII

NEW YORK—THURSDAY, DECEMBER 19, 1907—CHICAGO

No. 25

IN the transition from the pleasure to the commercial phase of automobiling, naturally slow at first, but destined to develop with increasing rapidity, the taximeter cab comes as the

natural forerunner. Despite numerous points of similarity between the touring pleasure car and the public service vehicle, there are still numerous lessons to be learned by constructors and operators in this line of commercialism. Europe plunged in nearly three years ago with gasoline taximeter cab services which, if not always the most profitable of ventures, have certainly given their promoters valuable experience and useful data for future developments. New York really only became interested in the taxicab movement this year, for though an electric cab service has been in operation for a long time it was not until 1907 that an electric company adopted gasoline and the first company was formed to operate gasoline cabs exclusively.

In the operations of the New York Taxicab Company, which, being the only one in the United States to operate gasoline cabs exclusively, and having 150 in use already and 150 more promised for May 1, may claim to be the most important, there are plenty of interesting features for the ordinary automobilist. The gray uniformed drivers who sit behind the steering wheel of the handy little Darracq cabs now so familiar on the streets of the city have been admitted into a sort of partnership with the directors of the company. The driver receives no wages, his remuneration being 20 per cent. of the net earnings of his cab, the amount being paid to him at the end of each day. In Europe taxicab drivers are generally paid a small wage, then given a percentage on a sliding scale basis, the percentage increasing with the amount of the earnings. The American plan is simpler, and is believed to work better than the foreign one by more completely uniting the interests of driver and controlling company. The method of control by means of the taximeter is too well known to need much explanation. Passengers are called upon to pay the amount registered on the dial of the instrument, the rate of fare being 30 cents for the first half mile, 10 cents every

additional quarter mile, and 10 cents for every six minutes' waiting. The only extras are return fare when the cab is taken above One Hundred and Twenty-fifth street and left, or when the Hudson or

East rivers are crossed. These extras have to be rung up on the dial before being collected, so that overcharging of the public is practically an impossibility, and disputes are unknown.

Naturally, there have been attempts in New York, just as in European cities, to cheat either the passenger or the company, or both; but he is a clever man who can dodge the taximeter. All that the passenger is called upon to pay is the fare indicated on the dial, and as every cent charged thereon is permanently recorded by the instrument and must be accounted for to the company, nothing is to be gained by overcharging, even if that were possible. The only way in which it would be possible to cheat the company would be for the driver and passenger to be in collusion, and for the former to accept an agreed sum without putting his recording instrument into operation. It is a dangerous proceeding, however, for the passenger might be an inspector of the company; further, too great a discrepancy between the total distance covered and the fares received would reveal itself automatically on the tell-tale indicator.

#### Work and Pay of the Taxicab Driver.

At the Taxicab Company's temporary station on Sixty-second street, Manager Alfred F. Camacho and his assistants have a busy time from 6 to 11 A.M. The first batch of cabs is sent out at 7 o'clock, each driver being given a measured quantity of gasoline, supplied with a daily report sheet, and allotted to a station at some hotel or railroad depot, to which he must report at the end of each journey. At intervals up to 11 o'clock other groups are sent out with a spick and span vehicle, a clean sheet, and a truth-telling recording instrument.

There is a freedom about the life of a taxicab driver which, together with the fairly liberal earnings, makes the profession a popular one, as is evidenced by the long waiting list. Each

"PROFESSOR" CAMACHO DRILLING WOULD-BE DRIVERS.

driver must be on hand to take charge of his cab on the appointed starting hour, must always report to the inspector at the hotel station he is attached to, but is not otherwise bothered with restrictions and regulations. As a newcomer, he is given one of the poorer stations, and gradually advanced to the better ones as he proves his ability. Some system of rotation is observed, so that the same men shall not always monopolize the stations where business is usually brisk. There are no regulations fixing the number of hours a man shall work, though naturally the company would find little need for the services of a man who habitually returned to the central station after three or four hours on the streets. Should he select, however, to go out early in the morning and not return until midnight, no objection would be made, providing he was on hand for the next day's run at his appointed hour.

Immediately on returning to the central station the driver turns in his daily report sheet, showing total takings, and is given 20 per cent. of that sum, minus the amount charged against him for gasoline supplied at cost price. As each cab covers on an average eighty miles a day, though as shown by the records there are some which attain as high as 150 miles in one day, 20 per cent. must give a very satisfactory day's wage, even when allowance is made for returning empty to the hotel station. By only being called upon to pay for the amount of gasoline consumed, economical driving is more directly encouraged than by the European system, under which an allowance of fuel is made on what the company considers to be average running, and is infinitely better than one wasteful London system under which the drivers are supplied free any quantity of gasoline they require. It is found that on an average eighteen miles to the gallon can

EIGHTEEN HORSEPOWER FROM THIS COMPACT POWER PLANT

be obtained from the four-cylinder engines, each vehicle consuming between four and five gallons per day. Considering the frequent stops and restarts occasioned by city traffic, this is a very satisfactory performance.

Adding tips to the percentages earned, there is probably a good deal of truth in the assertion of some drivers that they have netted \$50 in one week. Even \$5 a day, which is probably not much above the average, is sufficiently good earning for a driver of whom no mechanical experience is required to attract a reliable class of men. Should any defects have been noted during the day's running, they are reported on entering the station and attended to by the repair department; otherwise the cabs receive their ordinary toilette and have oil and gasoline tanks filled in readiness for the next day's business.

#### How One Tire Maker Vouches for His Product.

There is a valuable lesson which will not be lost upon the private automobilist in the system of payment for tires. Instead of buying tires for all their cars and maintaining stocks, the Taxicab Company has a contract with the Goodrich Tire Company by which payment is made for tires according to mileage. This relieves the Taxicab Company of much responsibility, for whether the tires give long service or break down after a short life, payment is only made on the mileage they furnish. It proves too that tires, erroneously supposed to be the most unreliable

DIFFERENTIAL AND TRANSMISSION IN ONE CASING ON FIXED AXLE.

part of the automobile, can be guaranteed on a perfect commercial basis. What might at first sight appear a complicated system is in reality exceedingly simple. An employee of the Goodrich Company is maintained at the Taxicab depot, every tire is numbered, and a complete record kept of its mileage performance. Naturally this would not be possible without the use of the taximeter. As all the cars have been put into circulation since the spring, it is too early yet to obtain figures regarding their tire mileage, no shoes having yet retired from active service, despite the rough usage the rear ones necessarily have to support through poor driving.

Punctures have no terrors for the taxicab man. If a tire fizzes out, he takes down the Stepney from its brackets on his right hand side, attaches it to the spokes of the wheel by clamps provided for that purpose, leaves the deflated tire in position, and in two minutes is off again. The Stepney, a British contrivance over which Manager Camacho is enthusiastic, consists of a tire mounted on a special rim with lugs for attaching it to the spokes of the road wheel. If a puncture or blow-out occurs when a passenger is in the car, the driver takes him to his destination on the Stepney, then, acting on instructions from the management, hurries to the Sixty-second street station, where the Goodrich man is in attendance. There is nothing, however, in the wheel to prevent it being run with perfect safety for any distance on either front or rear wheels.

The recording instruments are handled in a similar manner, each of the little clockwork boxes being hired from the Popp Company of Paris and maintained by a French expert always in attendance at the central station. In this branch of the taxicab business, also, foreigners have at present a monopoly, all the in-

struments used in this country being either of French or German origin, the former largely predominating.

**"Green" Drivers Are the Curse of Taxicab Companies.**

In any automobile cab undertaking the operating company is largely dependent on the skill or otherwise of its drivers, particularly during the first few months of operation. Even in France, where every driver of an automobile must hold a government certificate, the shareholders have had to bear the loss of scores of ruined gears and damaged cars due to reckless driving. Manager Camacho can tell stories which would be laughable, if they were not so costly, of young men provided with a badge from Albany and a hackman's license, who could be fooled with advice on crankshaft valve lubrication, and had the ability to put sets of gears out of business in much less time than any machine shop could produce them.

When the model station has been completed at Fifty-seventh street, between Eleventh and Twelfth avenues, a more complete system of breaking in green hands will be adopted than is possible now. Meanwhile, elimination is being carried on, those drivers who run out of the garage with a grinding clash of gears, or who fail to keep out of accidents, being asked to tender their resignation. Lubrication, simple as it is on the Darracq taxicab, appears to be beyond the comprehension of a few of the novices who are elevated to the seat behind a steering wheel, with the result that the engine suffers. One of the driving rules declares that the men must keep their engines smoking, and as there is, fortunately for the company, no law in New York against smoky exhausts, the majority of the drivers are generous in the use of lubricating oil.

Though a taxicab might do good service as a touring machine, the latter is not the best type for economical exploitation in city work. Either because they failed to realize the limitations of the average touring car for this special work, or because they were too busy to pay attention to the development of a new type, American firms have allowed the foreigners to obtain a considerable lead in the matter of taximeter cabs, with the result that both the New York Taxicab Company and the New York Transportation Company have gone abroad for their vehicles. The former company employs the special Darracq cab exclusively, importing them complete with body and recording instrument.

Compactness, ease of handling, and interchangeability have been sought in the new design. By producing the four cylinders, of 3.3 by 3.9 bore and stroke, in one casting it has been possible to obtain one of the most compact power plants on the market; the arrangement, too, allows of considerable simplification of the inlet, exhaust, and water piping, the exhaust manifold being cast integral with the cylinder block and equipped with radiating flanges. Water connection merely calls for two pipes, one connecting to the head and the other to the base of the cylinders. Ignition is by high tension Bosch magneto carried in an accessible but out-of-the-way position on the crankcase under the exhaust manifold. Sparking point is fixed, but may be retarded for starting by means of a trigger near the cranking handle.

Driving thus reduces itself to the action of steering, operating a clutch, brake and accelerator pedal and a throttle on the steering wheel. Gear changing is by means of a side lever operating in a gate sector. In addition to the switch and the pressure feed lubricator on the dashboard, there is a small lever by means of which the exhaust gases can be made to pass through a foot-warmer in the floor of the cab before reaching the open air. By reason of the short wheelbase and the narrowing of the chassis in front, the cabs are exceptionally easy to handle in traffic, and can turn around in an ordinary crosstown street of New York City without use of the reverse. When this series was designed, turning had to be given particular attention on account of the rigorous regulations of the London police on this matter.

Simplicity and interchangeability are believed to have been attained by uniting the differential and gearset in one housing carried on a solid fixed axle. The live axles, from each end of the gearcase, pass through the bored ends of the fixed axle to the

**A PUNCTURE, TWO MINUTES' DELAY, AND OFF AGAIN.**

road wheels. Dismounting the live axles is quickly accomplished by taking off six nuts on the hub of the road wheel and drawing the shafts out; to dismount the casing it is disconnected from the driving shaft, the three changespeed and one brake connecting rods are disconnected and the four retaining bolts by which it is secured to the fixed axle are withdrawn. When it is necessary to make repairs on the transmission the case can be taken down and another one put in its place with a loss of probably less than an hour. Three speeds forward and one reverse are provided, with direct drive on the high. The internal expanding foot brake is carried on an extension of the lay shaft outside the casing. The emergency brakes, operated by a side lever, are also of the internal expanding type on the road wheels.

Immunity from repairs, or at any rate a reasonable freedom

**EXPLAINING SOME OF THE ELEMENTS OF IGNITION.**

TRANSMISSION, DRIVE AND BRAKES ALL GROUPED TOGETHER.

from breakdowns, is of such vital importance that it will be interesting to note the experience of cab companies in this respect. It is rather early to form an opinion, for the New York Taxicab Company only commenced operations this year, but their report is that the vehicles are thoroughly satisfactory and will not entail unreasonable repair expenditure when undesirable drivers have been weeded out. A glance round the temporary repair shop at Sixtieth street shows plainly that unskilled driving is chiefly responsible for laying up cabs. A few of the more serious accidents have been caused by collisions with trolley cars and other vehicles—it is declared that all the users of the streets are not lovers of the taxicab, and will gladly take the opportunity of putting the small automobiles in a tight corner—but the majority are out of running through gears ground down as the result of the most unskilled handling. When all arrangements are completed for the importation of parts and the company is installed in its model station now under consideration, it is calculated that never more than 5 per cent. of the cabs will be held up for repairs, this including cases of accident.

#### HORSE DRIVERS FEEL AUTO COMPETITION.

New York's horsecab drivers went on strike for a period of twenty-four hours this week. They had demanded an increase of wages to \$15 a week for seven days' work, with twelve hours a day off duty. The officials of the men's unions finally agreed to accept \$15 with ten hours off out of each twenty-four and two additional hours for dinner and supper. Taxicab competition is declared to have made the horsecab business unprofitable.

SHOWING HOW LIVE AXLE IS WITHDRAWN FROM GEAR BOX.

#### NO CHAINS IN GREATER NEW YORK PARKS.

"Can't come on here with them chains on," said the bicycle policeman on duty last Monday morning at the entrance to Riverside Drive to an astonished automobilist who was bound uptown. There was some show of remonstrance at first, but the man at the wheel was soon made to see that resistance was useless, for the edict had gone forth by the Department of Parks that from that day forth automobiles equipped with tire chains must keep off many of the roads they most liked to frequent.

The Board of Parks had been struck with the fact that the highways under its control were in a deteriorating condition and immediately sent out the following order:

"No automobile or horseless or other vehicle wearing chains over the tires of their wheels shall enter the public parks or the traffic roads under the jurisdiction of the Board of Parks, without permission of the commission having jurisdiction. This rule and regulation shall take effect December 16, 1907."

As the commissioners' jurisdiction covers Central Park and nine of the most popular drives in Manhattan, thirteen parkways and drives in the Bronx, and all the important drives and macadam roads in Brooklyn, its effect on automobilists was considerable. Those who were unaware of the new order until

C. H. TANGEMAN IN THE NEW HOL-TAN RUNABOUT.

they were peremptorily told to stop—and they appeared to be many—had to choose between continuing on the selected highways without chains or choosing another route; the latter was more generally adopted.

One well-known automobilist, commenting on the regulation of the Board of Parks, appears to have voiced the sentiments of the vast majority of those owning and driving cars when he declared as follows: "The action of the authorities in barring tire chains from practically all the parkways in Greater New York is preposterous. I maintain that a half-inch toe calk on a horse driven into the pavement under the momentum of the weight of a 1,200-pound horse is necessarily of much greater damage to the roadway than the continuous tread of an automobile. Apart from the debatable question of damage done, what is a parkway for—to look at or to use? If it is built for use, then there is no reason or any justice in an arbitrary discrimination in favor of the horse. Why not put mufflers on the horses and require pedestrians to use tennis shoes or close the park entirely except for the use of city officials?"

It will be noticed that no mention is made in the regulations of any other anti-skidding device than chains. Steel studded tires and the numerous other appliances used on the automobiles with a view to overcome the tendency to skid on greasy surfaces are left unmolested.

GENERAL VIEW OF THE BERLIN "AUTOMOBIL-AUSTELLUNG," OPENED OFFICIALLY BY PRINCE HENRY ON DECEMBER 5.

### GERMANY'S NATIONAL SHOW.

BERLIN, Dec. 5.—In keeping with its aggressive policy of fostering the industry in every possible way, the German Government has always officially recognized the automobile show and royalty's gloved hand usually presses the button which nominally throws the brilliant collection of the best that the Fatherland and many of its competitors can show in the way of automobiles and accessories open to all who have the price of admission. No less a personage than the Kaiser himself inaugurated this custom, but for the past two years his place has been taken by his personal representative, Prince Henry, who did the customary honors to-day. The ceremony took place at 11 o'clock this morning, when the show was officially declared open.

The exhibits are located in "Exposition Hall"—a large building that lends itself to the purpose well and which is situated close to the Zoological Garden, in the very best quarter of the city. While German makers, as well as a German flavor, predominate, foreign cars are well represented, exhibits both from the Paris Salon and Olympia having been sent here intact. This is responsible for much of the striking contrast that is evident among the exhibits, for as a rule the home manufacturers have not gone to the expense of preparing elaborate booths. One of the chief distinguishing features of the Salon exhibits was their lighting effects, and, transplanted to this atmosphere, they are almost glaring in their brilliancy by comparison with those among which they are found.

But as a whole the show is representative of the German industry, as well as of the extent to which France, Belgium, Italy and England are interested in Germany as a market for their surplus products. Most of the prominent makes from each of the countries in question is represented, but there seems to be more or less of a feeling that competition is getting very keen for the Continental outsider. This, however, has not discouraged the American maker, and the Ford cars, which are becoming equally as well known abroad as at home, have been the object of as much attention here since the opening as they are said to have attracted at the Paris Salon a few weeks ago.

Details expresses in a word the technical end of the show, for

changes are confined practically without exception to those small matters of design and construction that generally escape any but the trained eye, and it would require a volume to attempt to describe the many small changes here, most of them of no particular moment, and some of them probably of doubtful value. An excellent example of the thoroughness of the Teuton is shown in the preparation of one of the exhibits of a safety system of fuel handling, which is illustrated by one of the photographs.

MODEL EXHIBIT, SHOWING MANNER OF INSTALLING FUEL SYSTEM.

## "SHALL SALON BE HELD ANNUALLY OR EVERY OTHER YEAR?"

PARIS, Dec. 10.—Shall there be a Salon in 1908? is the question which is agitating automobile France. Immediately the doors of the Grand Palais had been closed the Committee of the *Chambre Syndicale de l'Automobile*, which with the Automobile Club of France is responsible for the annual demonstration, met in Paris and decided to put the following question to all its members: "Shall the Automobile Salon be held annually or every two years?"

It will be several weeks before a decision is arrived at, but meantime those most interested are keenly discussing the pros and cons of the question, and public opinion is being turned into fixed channels. The enormous expense of annual shows as at present organized, their unsettling influence on trade, and the necessity for creating annual models, whether there is any room for improvement or need of change or not, have caused manufacturers to ask if it is not possible to break away from the annual exposition.

The Marquis de Dion, vice-president of the Automobile Club of France, declares that annual shows are a necessary evil, and that their burden is especially heavy upon the more important firms. Judging it from a sporting standpoint, or the viewpoint of the automobile user, it must continue to be held. To abandon it for one year would simply be to transport the automobile market to another country.

Rene de Knyff, of the Panhard Levassor firm, is strongly against a show in 1908, if an agreement can be arrived at with

the Royal Automobile Club for the suppression of the British show also. This he believes to be quite possible, for, English firms are no more enamored of an annual exhibition than are the leading French houses.

Emile Mors, of the Mors firm, is of practically the same opinion. If a determined effort is made by French makers to obtain an automobile show at intervals of two years, he believes that the British authorities will join them.

Henry Brasier declares emphatically that the industry is too advanced and types too well developed for there to be any necessity for an annual show.

It will probably be found that the question will resolve itself into obtaining an agreement with England, either for alternate shows in Paris and London or for shows every two years in both capitals, dates being arranged so as not to clash. Considerable rivalry has sprung up between London and Paris during the past three years, the former city, while admitting her inability to organize such a spectacular display as that at Paris, making every effort to wrest the business supremacy from her rival. If only the best interests of the industry were considered, doubtless some agreement would be arrived at whereby the Grand Palais and Olympia would be closed in 1908; but international jealousies must be reckoned with, and should the national body decide to remain idle next year it might not be easy to prevent some less responsible body uniting sufficient makers to hold a small but mischievous exhibition.

## TOURING RULES MORE DIFFICULT THAN RACING CONDITIONS.

PARIS, Dec. 7.—An international formula for touring competitions appears to be more difficult of attainment than the same thing for racing events. At the meeting of the International Association of Recognized Automobile Clubs, held at the Automobile Club of France, recently, the matter was discussed, but no other result arrived at than to refer the matter to a special committee. The international racing rules, adopted at the conference at Ostend in July, were confirmed, and the suggestion put forth, but apparently not acted upon, that they should be made obligatory.

The Ostend meeting, attended by representatives of the national clubs of England, France, Germany, Hungary, Italy, Spain, Sweden, Switzerland, Holland, Portugal, Roumania, Belgium, Denmark and Austria decided on a maximum bore of 155 millimeters for four-cylinder engines and a minimum weight of 1,100 kilos, without oil, gasoline, tools and spars tires.

As this has been confirmed by every nation except America, the Italian delegates are of opinion that its application should be made obligatory and not optional. European automobilists are at a loss to understand why America was not represented at the Ostend and Paris conferences. One of the two foreign A. C. A. delegates attended the meeting held after the French Grand Prix of 1906, but since then the United States has been dead to international automobile deliberations.

A project is now before the International Committee to appoint an International Racing Board from its members, to deal exclusively with the regulations for and conduct of international speed events.

Although England has not adopted for her only speed event the international rule she was so largely instrumental in framing, and America, according to cable reports received, practically adheres to the obsolete Gordon Bennett conditions, races under the 155 millimeter rule will be the feature of the coming season. Doubtless the adoption of a four-inch bore by the Royal Automobile Club of Great Britain can be accounted for by the strong

feeling existing in England against racing on the highways. Britishers have always tried to convince themselves that the Tourist Trophy competition was a touring event; when they abandoned the fuel consumption rules for a limited bore they endeavored to keep to vehicles of about the same power. To have adopted the international rules would have announced the race as a pure speed test, and doubtless diminished the chances of obtaining a course in the Isle of Man. Their policy will make the race a local and not an international event.

In addition to all the French firms making a practice of competing in international races, this year several who have not been at the starting line for some time will build cars under the 155 millimeter rule. Among them are mentioned Mors and Charron, one of the cars of the latter firm to be handled by Venus, mechanic of the late Albert Clement.

Belgium and England will help to increase the ranks, while Germany will be represented by Benz, in addition to Mercedes. All three Fiat cars are already on the road, and at least half a dozen French firms are sufficiently advanced to be able to test out very early in the year.

Contrary to previous years, the Ariel firm of England has produced its Grand Prix racers already and commenced road tests. The cars have four-cylinder engines of 150 millimeters bore, which it is calculated will give 125 horsepower at 1,500 revolutions. Other features are high-tension magneto, disk clutch, four speeds and reverse by sliding gear transmission, and shaft drive. Deasey, another Britisher building under the 155 millimeter rule, is declared to have his cars ready, but particulars are not available. Continental makers are not anxious to give details.

A meeting has been held between the Racing Board and the municipal authorities of Dieppe regarding the adoption of the Dieppe circuit for next year's Grand Prix. No official decision has been arrived at, but it is looked upon as almost certain that the same course will be used, the Dieppe district being willing to give a subsidy of \$10,000.

# CORRECT MANNER OF FOLDING AN INNER TUBE

**N**UMBERS of automobilists, especially among beginners, do not know how to pack inner tubes or how to carry them on their cars, writes Baudry de Saunier in *Omnia*. To fold a tube in the most satisfactory manner the valve should first of all be removed in order that the air may easily escape during the later operations; it is impossible to fold with valve in.

The tube should then be arranged, as shown in Figure 1, the operator placing himself at R. This work should be done on a table, a plank, or any flat surface, providing it is free from oil

SHOWING THE VARIOUS STEPS IN THE PROCESS OF FOLDING.

or any liquid, and especially from gravel or grit. If no table is available, it can be done by holding the tube against one's chest, but the operation is then more difficult and the operator's clothes are not improved.

Whatever may be the support, the tube should be rolled up as tightly as possible, beginning at the end farthest removed from the valve. The air is thus partly driven out through the open valve tube; the emptying of the tube, however, is not complete, owing to the bending of the tube at *bb* at the foot of the valve. While holding tightly the rolled part, *R*, with the left hand, draw to the rear from time to time the opposite end, *V*, to allow the imprisoned air to escape. Continue to do this until the tube is completely rolled, as shown in Figure 2.

Still holding the tube as tightly as possible, insert the valve and put on the cap *C*, screwing up as tightly as possible with the fingers, but not on any account using the pliers. The inner tube is now completely flattened, and it should always be brought into this condition (if it is not so already) every time it is desired to mount it on a wheel. When perfectly flattened the mounting of a tire is enormously simplified and at the same time it is largely preserved from nipping or blows from a lever or other tire tool. The results are well worth the little labor.

Next open the tube out again, as shown in Figure 3, the valve being in the center and uppermost. If you have any real care for your tires you will cover the valve with a rubber finger, *D*, similar to the rubber fingers sold at all drug stores. If one of these is not available you will make one out of a piece of cloth. This covering protects the tire against the ill effects sure to arise when the valve is allowed to rub against the rubber.

Now fold each end of the tube inwards towards the valve, as shown in Figures 4 and 5, forming the flat package, *M*, which should be secured by a couple of tapes, or, better still, by a couple of rubber bands made out of strips of an old tube.

If the tire is punctured or without valve, it is useless to attempt

to fold it, for although you have driven out the air it will enter again by the hole or through the valve as soon as pressure is removed. Thus, as soon as it has been rolled as shown in Figure 2, fasten it securely with tape in order that it may not lose its shape, and leave it in that condition. The particular advantage of this is that it enables at a glance to distinguish between perfect and imperfect tubes, the perfect ones being folded and the punctured ones rolled.

Each tube should be placed in one of the waterproof bags specially made for that purpose. This is only a detail, but it is a very important one. The bag protects the tube better than any other kind of packing, preserving it from contact with tools, or other rough objects, and keeping it out of the way of oil and water. If a handful of French chalk is thrown into the bag the tube automatically chalks itself and prepares itself for being mounted within the tire. If no bag is available, the tube should be wrapped in a piece of clean cloth and secured with a string. When on the road carry your packed tubes in a separate box and not in the common compartment where oil cans and tools struggle for the most comfortable position.

## TWO SUBSTITUTES FOR THE TIRE PUMP.

Substitutes for the tire pump have generally been put on the market in the form of mechanical devices designed to be operated by the engine; their success has only been partial, users as a rule being unwilling to accept the responsibility of the extra complication. Compressed air tanks have met with some success, and doubtless will come into general use when minimum weight has been attained. A new principle has been adopted

PORTABLE TIRE PUMP OPERATED FROM ENGINE FLYWHEEL

in an automatic inflator produced by Grovelle & Arquembourg, the French firm of radiator makers. Here the engine is employed for inflation, but there is no extra fixed mechanism on the chassis and simplicity is carried out to a fine degree.

FIXED TIRE PUMP DRIVEN BY FRICTION FROM FLYWHEEL.

In the illustration, which has been reproduced from *Omnia*, the complete apparatus is shown ready for use. It consists of a small portable pump, the piston of which is united to the leather faced flywheel *R* by the connecting rod *S*. *M* is merely a wooden handle connected to the body of the pump by the pin *m*. A short length of piping, *T*, carrying a pressure indicator, *U*, is connected to the body of the pump at *N*. At the extremity of the pipe a length of rubber tubing is connected up at *Q* and carried to the tire valve. To put the instrument into operation all that is necessary is to connect the tubing to the valve, lift out the floor boards and place the flywheel *R* on the flywheel of the engine. When the required pressure is shown on the indicator the operation is stopped, the wooden handle disconnected, and the pump stowed away in the tool box. All that is necessary to keep the pump in condition is to take down the piston from time to time and spread a little vaseline over the rings.

Although taking its power from the flywheel of the motor, the Vadam mechanical pump, another European production, is of quite a different order. As will be seen from the illustration reproduced from *The Car*, it is attached to the frame in such a way that the wheel of the pump is driven by friction from the engine flywheel. Attachment is merely a matter of bolting a bracket of 1 inch by 1-2 inch wrought iron to carry the inflator and above it the support for the adjusting screw, the leather faced wheel being brought into or out of engagement with the engine by means of a simple thumbscrew arrangement. The pump itself consists of eight cylinders containing four double pistons, which are situated round a center disk grooved to engage with a roller fitted to each set of pistons. The disk is directly driven on ball bearings by the driving wheel. With a sufficient length of piping, connection is made to any wheel.

"BOB" FITZSIMMONS AT THE WHEEL OF THE WINTON.

The celebrated ex-champion pugilist is a devoted admirer of the Winton "Sixteen-Six." Immediately back of Fitzsimmons is seated John S. Johnson, famous as a cyclist and skater, who is now connected with the Winton Branch at Pittsburgh. **A.**

## THE AUTOMOBILE CALENDAR.

### AMERICAN.

#### Shows and Meetings.

- Dec. 14-21.....—St. Louis, Mo., Jal Alal Building, Second Annual Auto Show, St. Louis Automobile Manufacturers' and Dealers' Association. D. M. Strauss, manager.
- Dec. 28-Jan. 4.....—New York City, Madison Square Garden, Importers' Salon. C. R. Mabley, manager.
- Jan. 14-18.....—Hartford, Conn., Foot Guard Hall, Hartford Automobile Dealers' Association.
- Feb. 1-8.....—Providence, State Armory, Automobile Show. Frank M. Prescott, manager.
- Feb. 10-15.....—Detroit, Light Guard Armory, Tri-State Automobile and Sporting Goods Association, Seventh Annual Show.
- Feb. 17-22.....—Cleveland, Central Armory, Annual Show, Cleveland Automobile Dealers' Association. George Collister, manager.
- Feb. 21-29.....—Newark, N. J., Orange A. C. Building, New Jersey Automobile Trade Association and New Jersey Automobile and Motor Club.
- Mar. 7-14.....—Boston, Mechanics' Building and Horticultural Hall, Boston Automobile Dealers' Association. Chester I. Campbell, manager, 5 Park Square.
- Mar. 9-14.....—Buffalo, Convention Hall, Sixth Annual Automobile Show, Automobile Club of Buffalo. Dal H. Lewis, manager.
- Mar. 21-28.....—Toronto, Canada, St. Lawrence Arena, Automobile Show. R. M. Jaffray, manager.
- Apr. 5-12.....—Montreal, Canada, Arena, Third Annual Automobile and Sportsman's Show. R. M. Jaffray, Mgr.

#### Motor Boat Shows.

- Jan. 1-8.....—Chicago, Coliseum, National Association of Engine and Boat Manufacturers. Chester I. Campbell, manager, 5 Park Square, Boston.
- Jan. 25-Feb. 1.....—Boston, Mechanics' Building, National Association of Engine and Boat Manufacturers. Chester I. Campbell, manager, 5 Park Square, Boston.

# PRINCIPLES OF SPEED AND DISTANCE RECORDERS

By CHARLES B. HAYWARD.

If he were to give it a thought, the why and wherefore of the neat little instrument adorning the dashboard of his car that mutely indicates speed and mileage would considerably puzzle the average man to whom mechanics are a riddle. But he seldom lets it bother him—any more than does the train of action in his watch which transforms the pent-up energy of the main spring into the accurately measured beats of the second hand,

FIG. 1.—Internal view of the Jones Speedometer, showing the essentials of a typical centrifugal instrument.

and if interrogated on the point, doubtless his answer would consist of "Oh, something like the inside of a watch." So far as finish, delicacy of its component parts, accuracy in operation and a few kindred qualifications are concerned, a good speedometer may be correctly compared with a watch, but there the parallel ends. The chief difference between the two is to be found in the fact that the watch is an entirely self-contained piece of mechanism, while all speed and distance recording instruments naturally require power from an external source for their operation, in view of the fact that they do not operate independently, but merely as a part of the vehicle to which they are attached. Familiarity with mechanical movements and principles makes it evident that such a device may be constructed with any one of several differing principles as its basis of action, but in the majority of instances that of the time-tried ball governor of the steam engine has been utilized as the groundwork, so to speak. In other words, centrifugal force. Just as the elevation of the two solid spheres of metal of the familiar two-ball governor is made to cut off the steam and reduce the speed of the engine when the latter exceeds a predetermined limit, so the tendency of any suspended weight

to fly away from its point of suspension, or attachment, when revolved at a high rate of speed, provides the actuating force which moves the pointer of a great many of the speedometers on the market to-day. Instead of taking the same form as that of the steam-engine governor, however, the chief moving part of the speed-indicating instrument is generally made annular in shape, taking the form of a wheel with a very heavy rim and but a single pair of spokes passing diagonally across its center and serving to pivot it on the shaft, which is directly

FIG. 2.—Cross sectional elevation of the Index Speed Indicator, illustrating the arrangement of a vertical centrifugal type.

driven from the forward wheel. As is the case with the watch, here the comparison between the governor and the speed indicator also comes to an end, because the conditions under which

the two devices are designed to operate are about as widely separated as the poles, and the chief difficulty in designing an instrument that would accurately record speed under the rough treatment inevitable when placed on such an unstable platform as the automobile was found in the shocks to which the latter is continually being subjected when run over rough roads at high speeds. To control the centrifugal force set up by the heavy annular weight when revolving at high speed, a stiff restraining spring is provided. Against this the weight must act before it can move the indicating pointer on the dial. As the speedometer is usually "geared up," that is, designed to run at a much higher rate of speed than the wheel to which the operating gears are attached, the instrument generally attains sufficient momentum in its heavy revolving member to accurately indicate speeds as low as five miles an hour, though, of course, it begins to act long before that figure is reached, and as the acceleration of a heavy, rapidly moving body is uniform, the

FIG. 3.—Part sectional view of the Loring Speed Gauge, which is of the vertical type, closely resembling a ball governor.

movement of the hand is gradual and not jerky, as might at first appear to be a necessary sequence. To transmit the movement of the revolving member in one plane to that of the indicating hand, which lies in another, various forms of intermediaries are employed. These sometimes take the form of an arm moved by gearing, though this is one of the points in which some of the instruments of the centrifugal type are distinguished by their simplicity and others by their complication. It will be evident that inertia and momentum are two factors of great importance that the designer of the speedometer must figure with when calculating the size of the parts of the instrument, as the latter's components must be neither difficult to get under way nor hard to bring to a stop, once in movement. For this reason the parts are of a size and weight that make the comparison to the mechanism of a watch justifiable by the casual observer.

FIG. 4.—Details of the mileage-recording mechanism of the Jones Speedometer, having trip and season dials.

Credit must doubtless be given to the Jones Speedometer as the pioneer in its class, and as the principle upon which it operates is that of a number of other instruments since placed on the market, a detailed description of its working will apply, in large measure, to that of the others, barring a few details that will be noted later. It may most aptly be designed as a

FIG. 5.—Interior of the Warner Auto-Meter revealed, showing the relative positions of the magnet and field ring.

horizontal centrifugal type, as the shaft and ring governor are placed in that manner, the drive being taken through the small bevel pinion seen at the right-hand side. The cut, Fig. 1, illustrates the heavy brass ring, which constitutes the chief factor in the operation of the instrument in the position it assumes when stopped, the hand being at zero. This ring swings freely on pivots mounted on the horizontal spindle driven by the bevel

FIG. 6.—The Springfield Motormeter—a true ball governor.

gear, while connected to the ring by a light steel link is a sleeve, free to slide along the spindle. The left-hand end of this sleeve is flanged to form a collar, which is connected to the counterbalanced pointer through the levers shown, and which serves to transmit the movement of the ring at different speeds to the latter.

When revolving, the brass ring has a tendency to assume a position at right angles to the spindle, thus drawing the sleeve mentioned along the latter against the action of the controlling spring, so that the finger engaging with the collar on the left-hand end of the sleeve is carried with it. This part of the mechanism is not visible in Fig. 1, but it in turn engages the peculiar-shaped cam shown directly beneath the collar. The cam in question is pivoted on the sliding lever shown, and this in turn is attached at its right-hand end to a small crank on the indicating hand, the pointer spindle being controlled by a hair spring.

It will be evident from this that the faster the spindle turns, corresponding to an increased speed on the part of the car, the greater will be the tendency of the brass ring to take up a position at right angles to its shaft. But, bearing in mind the varying tension or compression of a spring with an increase in its load, the question will naturally arise, "How can the instrument be made accurate at all speeds over a range from a few miles an hour up to a mile a minute?" In the first place, the dial is calibrated according to the varying control of the spring at different speeds, the divisions accordingly not being uniform over the entire scale, and, secondly, an auxiliary spring is provided. This second spring is carried on the pivots of the ring, and comes into action when the ring assumes an intermediate position; it is not visible in the illustration.

The mechanism of the mileage recorder of the Jones Speedometer is illustrated in Fig. 4. This device is driven from the main spindle carrying the brass ring by means of a short vertical shaft having gear-teeth cut on its lower end, and engaging with a worm at its upper. The upper end of this vertical shaft carries a pin, set eccentrically, which operates the counting mechanism through a pawl acting on a ratchet wheel. The latter carries a finger, which in the course of its rotation operates the upper train of five intermittent gears. These gears are accurately maintained in position by means of a spring fastened to the plate, the object of this spring being to throw the gears over the center quickly and index them uniformly, so that the figures indicating the mileage always stand centered in the dial openings. The lower train of intermittent gears is also actuated by the finger on the ratchet wheel, and carry the figure disks for the trip mileage. When it is desired to reset this part of the indicator at zero, pressing a small plunger shown protruding through the lower part of the case in Fig. 1, forces the pawl out of engagement, allowing this gear train to be acted upon by the spring, and turning each

FIG. 7.—The Lipman combined Electric Generator and Odometer.

figure disk until halted by the stop springs on the back of the device. The maximum speed-indicating device consists of a dummy hand and small pin which is engaged by the regular pointer and carries it along to the figure represented by the highest speed attained. As it is carried around the dial, the dummy hand winds up a small hair-spring, but this is prevented from returning the hand to zero when the pointer falls back, by means of a second spring. The latter may be released by pressing a button, and the hand then returns to zero.

The foregoing is descriptive of the manner in which both the speed and distance-recording apparatus of an instrument of the centrifugal type operates, but even though based on the same principle, other instruments vary considerably in the arrangement of their essentials. For instance, the Index Speed Indicator, shown in Fig. 2, is of the vertical centrifugal type in which the spindle is practically a continuation of the driving shaft, thus giving it the advantage of eliminating the bevel gear drive, in addition to simplifying the intermediate steps in the transmission of the movement of the ring governor to the indicating pointer. It will be seen that a system of articulated levers connects the ring governor to a second spindle in the same plane as the first but not revolving with it.

FIG. 8.—Details of the Warner drive connection.

FIG. 9.—Swivelling drive connection of the Stewart instrument showing its range of movement.

At its upper end this second spindle, which runs on an independent ball bearing, carries a worm engaging with a small pinion at the right, to which is eccentrically attached the lever which serves to set the pointer in motion.

The Loring Speed Gauge, which is also of the vertical centrifugal type, represents a closer approach to the time-tried principle of the ball governor than any of those yet mentioned. Its vertical driving shaft enters the case direct without any intermediaries in the shape of bevel gears, and is supported on ball bearings. To this shaft is keyed a small balance wheel, having two weights pivoted at opposite points on its periphery. Under the action of centrifugal force the weights move outward and downward, raising a slotted sleeve by means of pins and rollers, this vertical motion again being transformed into a rotary one through several steps, terminating at a nut turning on a quick-pitch thread. This nut is prevented from rotating, and the indicating pointer is attached directly to the upper end of the threaded spindle which turns through it, thus making the only connection between the rotating shaft and the indicating part of the instrument, a hardened steel pin placed directly at the center of rotation, as will be seen by referring to the exterior view of the Loring shown in Fig. 10. It will also be noted that in this case the odometer is practically an independent instrument, being carried at the side.

FIG. 10.—The Loring Speed Gauge as it appears on the dashboard of a car.

The Springfield motometer is another instrument of the vertical centrifugal type, but its construction is so simple as to scarcely call for any extended description of its working, the sectional drawing, shown in Fig. 6, illustrating it in its entirety. In fact, it is a ball governor, pure and simple, the spring-controlled weights shown operating a second spindle carrying the indicating hand, and which is free to move vertically. From this it will be apparent that the action of the governor is direct, there being no intermediaries in the shape of multiplying or reducing devices, which accounts for the distinctive type of dial employed. The odometer is a separate instrument and is driven from the main spindle of the instrument through worm gearing.

A centrifugal type of instrument that differs radically from those already described is the Veeder Tachodometer. In this simplicity has been carried to its extreme. The centrifugal force engendered in a liquid confined in a small vessel, when agitated by a rapidly revolving paddle, constitutes the principle of the Veeder and accounts for the fact that it has but one moving part. This consists of the driving shaft, to which is permanently attached a small paddle-wheel, revolving in a predetermined quantity of colored liquid which is forced upward through a glass tube from which the air has been exhausted. This tube is fastened to an accurately calibrated scale, the reading being similar to that of a thermometer—an instrument which the Veeder resembles at first glance. It has the advantage that all its operations are based on the natural laws of gravity and centrifugal force, and having but one moving part, it remains permanently accurate regardless of the length of its service.

FIG. 11.—Thermometer-like appearance of the Veeder Tachodometer.

This suffices to sum up the various types of centrifugal instrument at present on the market, but does not comprise them all by any means. For instance, there are the Stewart and American instruments of the horizontal centrifugal type, both the product of one concern; the Hicks Speed Indicator, in which the intermediate mechanism between the ball governor and the hand has been simplified to an extent where it consists of but two springs; the Lea Speed Meter, which is of the vertical centrifugal

FIG. 12.—The Lea Speed Meter, showing record of maximum speed hand.

type and is extremely simple in its operation; the "Perfect" speed indicators, made by one of England's oldest watch-making firms, and the "Ever-Ready," also of the centrifugal type and which are made in quite a variety of styles. Being the product of a concern that has devoted its attention exclusively to the manufacture of chronometers and other instruments of precision for several generations past, it naturally follows that the "Perfect" instruments should be distinctive in design and construction. A series of controlling springs is employed, thus

making the instruments accurate at all speeds, a quality that is further contributed to by the fact that each dial is hand made to correspond to the instrument for which it is intended. The "Velocimeter" is another centrifugal instrument, which, as its name signifies, is intended only to indicate speed.

**Electrical and Magnetic Instruments.**

All of the instruments thus far considered are of purely mechanical types, and as such afforded great play for the ingenuity of the designer in making them simple or complicated, but it is only by substituting such forces as magnetism and electricity for mechanical operation that the extreme of simplicity is realized. The Warner Auto-Meter utilizes the magnetic principle, and the sectional view of its interior, shown in Fig. 5, illustrates the method of its working. The actuating force consists of a magnet which is shown attached directly to the ball-bearing driving shaft where it enters the case. Supported in sapphire pivot bearings just above the magnet is a field ring, and attached to the latter is the dial, which is of aluminum and annular in form. This field ring completes the magnetic circuit, and it will be apparent from the description thus far that there is no mechanical connection whatever between the driving shaft and

FIG. 13.—The American—a low-priced instrument made by the manufacturers of the Stewart.

FIG. 14.—The Hicks self-contained speed indicator, mileage recorder and clock.

displacement caused by the turning of the dial, thus making it possible to mark the latter with uniform spaces for the various speeds. As the field ring and the dial are combined and the magnet acts directly upon the latter, there are but two parts to the instrument, barring the case, so that the great simplicity of the magnetic principle will be evident.

But the speed indicator reduced to its very lowest terms of simplicity is to be found in the Lipman electrical instrument. Scientific investigation extending over a long period of years has made possible the measurement of an electric current to a degree of accuracy unattainable in other fields, and this, in a word, represents the principle of the Lipman. It consists of a small generator driven directly from the front wheel

FIG. 15.—The Jones Speedometer and clock combination illuminated by a small electric light.

of the car, and the indicating portion of the instrument, which is nothing more nor less than a millivoltmeter. The generator is of the simple, permanent field type, with a single horseshoe magnet and H armature, and is wound to generate a small current at a potential of one volt, when turning at a speed equivalent to 60 miles an hour on the part of the car. As the generator is of the induction type, employing no brushes or commutator, and the usual flexible shaft is replaced by a cable conveying the current to the indicator, it will be evident that the number of small parts liable to deflection has been reduced to its possible minimum in the Lipman. The driving shaft of the generator is of hardened steel, accurately ground, and runs on ball bearings, while the entire device is inclosed in a moisture and dust-proof case. As the voltage generated is always directly proportional to the speed and is sensitive to the slightest variations in the latter, the instrument can be made very accurate, the dial being calibrated to read in miles per hour, instead of fractions of a volt. The generator is directly attached to the steering knuckle of either of the front wheels and is combined with a season and trip odometer.

FIG. 16.—The Ever-Ready Universal, representing a very compact type of combined instrument.

While the power necessary to drive a speed-indicating instrument is naturally an entirely negligible factor, that of maintaining the drive in efficient working condition has often proved to be quite the reverse, particularly in earlier days, when the condition of this essential as revealed by cars finishing endurance tests was often deplorable. With the exception of the Lipman electrical instrument, in which the generator alone is driven direct, the power to operate the device is conveyed from a gear fastened to the front wheel through a second and much smaller pinion and a flexible shaft, so that the governor ring, or ball governor, of the speed-indicator revolves several times as fast as the front wheel of the car. This, however, finds an exception in the case of the Perfect, which is friction-driven at a speed but twice that of the car wheel, thus distinguishing it from the majority of other centrifugal instruments in two important respects. Trouble was at first experienced with the flexible shaft coupling at the front wheel, taking the shape of numerous breakages, which have been overcome by a number of ingenious devices, two of which are shown by Figs. 8 and 9, the first being a feature of the Warner, and the second, part of the Stewart and American instruments.

**Something About the Speedometer's External.**

It has been facetiously remarked that the variety of speed and distance-indicating instruments on the American markets range in appearance "all the way from a steam gauge to a cash register," and when some of the types that have come and gone are recalled, the remark does not appear entirely unjustified. Simplicity and neatness of external appearance are, however, as great an asset, where such an instrument is concerned, as its accuracy and durability, and this will be borne out by casual observation of the dashboard of the average car and the instrument that adorns it. Within the past year or two, however, it is noticeable that instruments greatly exceeding in size and apparent complication those of former days, are becoming more prevalent. But this is for an entirely different reason. It has become common to combine several instruments in one, in keeping with the tendency to clear

FIG. 17.—A most elaborate combination of Perfect speed and mileage recorder, clock, barometer and compass, all mounted on the same base.

the dash of the modern car of all superfluous attachments, so that now it is nothing unusual to find the timepiece and speedometer combined, as for example, in the Jones combination instrument shown in Fig. 15, and the trend in this direction has been carried to the extent illustrated by the Perfect speed indicator, clock, barometer and compass, and this does not represent the extreme attainable, as a signaling device might be added, even to this elaborate array. A combined clock, speed indicator and signaling device of the same make is illustrated in Fig. 18, which also serves to show the manner in which the readings may be duplicated by the use of a second instrument placed in view of the passengers, but driven from the same shaft. In addition to the types of speed and distance-recording instruments familiar to the autoist by their presence on the great majority of pleasure cars, there is another class which will shortly come into use in numbers, but which are, after all, designed more for use on the commercial vehicle than on the pleasure car, particularly as they are equally applicable to the horse-drawn or power-driven vehicle. One of the first of these to make its appearance was the Phelps Vehicle Recorder, which is being marketed by the same concern that handles the Lea Speed Meter. It differs radically from others in that the making of its record of stops, starts and elapsed time of stopping and running, night and day, requires no mechanical connection with any moving part of the vehicle itself. The record is made on sensitized paper disks.

In addition to the Phelps, there are two, or probably more, instruments which have been pretty thoroughly tried out in service and have proved satisfactory, but as yet have not been placed on the market. They are intended for pleasure as well as commercial use, and consist of a combined chronograph and speedometer. The chronograph record takes the form of a strip of paper, showing all stops, the distance covered, rate at which it was run, and other particulars which make it easy to keep a close check, either on a chauffeur or the driver of a vehicle.

FIG. 18.—Perfect speed, distance and time recorder combined with signaling device, arranged to show in two places from the same drive.

# LETTERS INTERESTING AND INSTRUCTIVE

## RESTORING SCRATCHED CELLULOID FRONTS.

Editor THE AUTOMOBILE:

[1,017.]—Will you kindly republish the two articles printed a year or two ago, giving (1) the process for making clear again celluloid fronts which have become cloudy, and (2) the temperatures at which different strength solutions of calcium chloride freeze? If you do not care to republish, kindly advise me of the dates of these two articles.

Denver, Colo.

C. H. HOWE.

Editor THE AUTOMOBILE:

[1,018.]—Some time ago (about Spring, 1907), under the head of "Letters Interesting and Instructive," I noted an article entitled "How to Restore the Brilliancy of a Scratched Celluloid Window." Can you refer me to the number in which this article appeared?

Bridgeport, Conn.

A. A. LYMAN.

In answer to the foregoing inquiries we are reproducing herewith the answer of the correspondent who came to our aid in this matter. His instructions are as follows:

In a recent issue of "The Automobile," that of December 20, 1906, one of your readers asked, in question 508, what could be done to restore the surface and transparency of a celluloid window that had become scratched and dimmed by use. You admitted your inability to solve the problem, and said you would be pleased to have any reader help the inquirer out. I think I can do this. If a worn sheet of transparent celluloid is varnished on the worn side (on both sides if both sides are worn) with a very thin, even coat of any transparent varnish, it will recover practically its original condition and appearance. Probably the best varnish for the purpose is made by dissolving a quantity of transparent celluloid in acetone, making the solution exceedingly thin, and applying more than one coat if necessary.

HARRY CLINTON.

Asbury Park, N. J.

Regarding the subject of anti-freezing solutions, herewith are formulæ that will be found efficacious:

Calcium chloride—Ten per cent. Solution freezes at 15 above zero, Fahrenheit.

Calcium chloride—Fifteen per cent. Solution freezes at 5 above zero, Fahrenheit.

Calcium chloride—Twenty per cent. Solution freezes at zero, Fahrenheit.

Calcium chloride—Twenty-five per cent. Solution will not freeze at zero.

Wood alcohol—Ten per cent. Solution freezes at 15 above zero, Fahrenheit.

Wood alcohol—Fifteen per cent. Solution freezes at 5 above zero, Fahrenheit.

Wood alcohol—Twenty per cent. Solution freezes at 2 above zero, Fahrenheit.

Wood alcohol—Twenty-five per cent. Solution freezes at zero.

Glycerine—Ten per cent. Solution freezes at 20 above zero, Fahrenheit.

Glycerine—Fifteen per cent. Solution freezes at 15 above zero, Fahrenheit.

Glycerine—Twenty per cent. Solution freezes at 8 above zero, Fahrenheit.

Glycerine—Twenty-five per cent. Solution freezes at 5 above zero, Fahrenheit.

Wood alcohol and glycerine soften rubber connections after a time, but this would be a small matter.

## DRIVING REGULATIONS IN NEW YORK CITY.

Editor THE AUTOMOBILE:

[1,019.]—Would you please send me circulars concerning rules of driving an automobile in New York City? If not able to furnish me with such, inform me where I can obtain them.

Cohoes, N. Y.

THOMAS ROULIER.

These rules are obtainable on application to the Police Department, City of New York, and will be forwarded gratis from the Central Office, 300 Mulberry street, New York.

## POWER CONSUMED IN INITIAL CRANKING.

Editor THE AUTOMOBILE:

[1,020.]—I thank you very kindly for your reply to my recent question in regard to the amount of power required to produce a revolution of a gasoline engine. It was, no doubt, through my not having made myself clear that you misunderstood what I wanted.

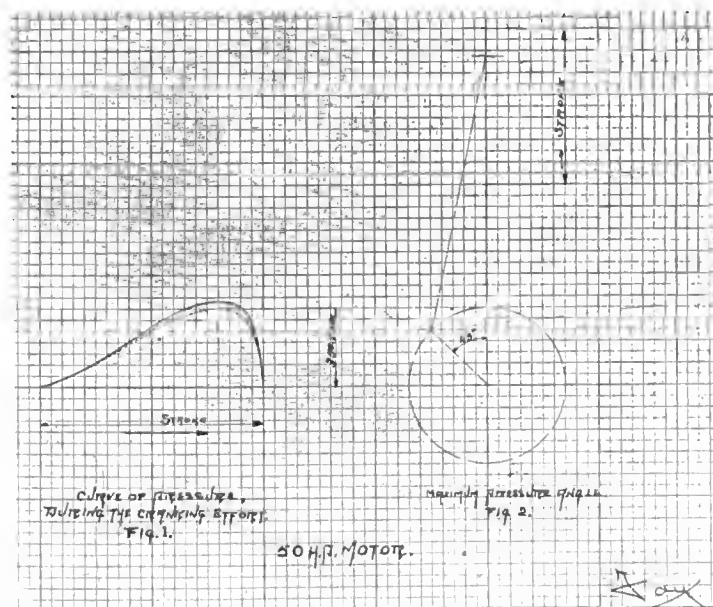

I wished to know the amount of power required to produce the initial revolution of a gasoline engine of 50 horsepower, with a compression of 70 pounds to the square inch, the majority of automobile engines not having over 50 horsepower, nor a compression higher than 60 or 70 pounds. You also gave the amount required at 1,000 r.p.m., whereas I desired this information for the initial revolution to start the engine.

I inclose envelope herewith for reply, also ten cents, for which please send me a copy of the October 31 issue, which I was unable to obtain, my dealer having sold out his supply.

H. C. ARNOLD.

South Framingham, Mass.

As it is customary to publish all letters of general interest in this department, the reply is given herewith instead of being forwarded by mail, the delay in answering being accounted for by the Chicago show intervening. It may be

FIGS. 1 and 2.—Illustrating the curve of pressure during the cranking stroke, and the maximum pressure angle with reference to the stroke.

well to point out that that question of the power of the motor is not involved, at least not directly, although it happens to be the case that the torque of a motor is very nearly the same as the initial pull in starting the motor. As your inquiry in its present form involves the mathematics of the subject, we think a curve illustrating it is of considerable interest, and herewith append an illustration of one that has been kindly prepared by Thomas J. Fay, who has also compiled the formula for calculating the pull. The curves, Figs. 1 and 2, were charted to show at what point in the revolution the maximum pull would come, beside indicating the characteristic of the pressure curve during the cranking revolution.

The cranking pull on a 9-inch crank, for a 50-horsepower motor of the usual automobile type, would be maximum as follows:

$$P = \sin. a \frac{C \times T}{L} \times \% C = 375.5 \text{ approximately for the}$$

motor in question. In this formula:

P = the pull in pounds at 9 inches radius.

a = the angle of the crank arm to the connecting rod.

C = cold compression in pounds per square inch.

%C = the percentage if the compression corresponding to the given angle of the connecting rod.

Naturally the length of the connecting rod will affect the result in some measure, in addition to which no calculation will give absolutely exact results.

### INFORMATION ON CHANGE-SPEED GEARING?

Editor THE AUTOMOBILE:

[1,021.]—In a course on the subject of gas engines, each is required to write a paper on some subject pertaining to them. Mine chanced to be "Change of Speed Gearing." I find it difficult to get any information on that subject, and could you refer me to any articles in your paper or elsewhere on that subject? JAMES W. WAITE.  
Golden, Colo.

Articles on this subject appeared in THE AUTOMOBILE in the following issues: July 12, July 19, July 26, August 2, 1906. It would be necessary to have reference to a file or bound volume of the paper to obtain these numbers and various other articles on the subject would be found by looking through it. A general article also appeared in the issues of May 9 and May 16, 1907, but as few of the back numbers of THE AUTOMOBILE are in print, doubtless you would find some such work as "Self-Propelled Vehicles," by Homans, much better suited to your purpose, the necessary information being concentrated in a few chapters, instead of being scattered through a number of papers.

### CAN ANYONE HELP THIS INQUIRER?

Editor THE AUTOMOBILE:

[1,022.]—I have been told that J. C. Haschke, of Chicago, Ill., has a patent compound storage battery, and an official test was made on the 10th of April, 1907, and this touring car and battery was illustrated and described in all the scientific and automobile papers in the world. Have you described this car and battery in one or more of your magazines? If so, please give me the number and I will send money order covering the amount, as I am anxious to get all the reading matter that I can in regard to it.

Millis, Mass.

C. E. DANIELS.

We regret to be unable to help you out and must confess our ignorance of Mr. Haschke's battery. If any of our readers are better informed on the subject, or were present at the test in question, we shall be pleased to publish their communications or place them in direct touch with you.

### WHY NOT THE 8-CYLINDER "V" TYPE MOTOR?

Editor THE AUTOMOBILE:

[1,023.]—While you are discussing four and six-cylinder motors, what is the reason that the eight-cylinder type has not been used? It could be built more compactly and with no more parts than a six, while its torque would be more even than either, inlet passages could be shorter, and other advantages are apparent. I think the Marmon is the only one built in this country, and they do not seem to be advertising it this year.  
Cleveland, O.

GEORGE S. CASE.

Probably the most practical reply to your question is to be found in the fact that there is a demand for the six-cylinder motor, but little or none for the eight-cylinder of the type you mention. It embodies all the advantages you set forth, but this does not make people who buy cars want it, and that is the only reason manufacturers are now building six-cylinder cars.

### FROM GRAVITY TO PRESSURE FUEL FEED.

Editor THE AUTOMOBILE:

[1,024.]—I am up against a proposition I do not know how to handle. My gasoline tank is now above my carbureter, and I want to hang it below the frame. In doing this the bottom of the tank will be 18 inches below the float level in the carbureter. Now, how am I going to force the gasoline to the carbureter? Will check valve exhaust pressure work if I cut in between the motor and muffler? I have a Powell muffler, and will I get pressure enough to have a sure and dependable feed?  
Grand Haven, Mich.

CHARLES BOYDEN.

You can install either a pressure-feed system or a small pump. The former is most commonly used on cars having tanks below the carbureter level. The exhaust manifold is tapped, generally

just back of the motor, and a check valve inserted. As the pressure required seldom exceeds two pounds to the square inch, there is no difficulty in obtaining all that is needed in this manner.

### WHY AN L. T. MAGNETO MUST BE TIMED.

Editor THE AUTOMOBILE:

[1,025.]—Will you kindly inform me if it is necessary to time a low-tension magneto in replacing it on a car in order to have it work properly? I have had the engine of my 15-20-horsepower Darraco taken down, and in doing so had the timing gears deranged. The man I employed to retime them claimed that the magneto had to be timed also, and proceeded to do it, but failed to make it work and claimed that the magneto was demagnetized. I cannot understand the failure, inasmuch that it had given me entire satisfaction up to the time of the engine being taken down. I have always been under the impression that a magneto supplied a continuous current and did not require to be timed.  
New York City.

VICTOR F. PELIN.

It is quite essential that the low-tension magneto should be timed with the engine in order to give satisfactory service. Your impression that such a generator supplies a continuous current is erroneous. A magneto, properly so-called, generates an alternating current which fluctuates from zero to its maximum, first in one direction and then in the other, this being known as its *cycle*. For incandescent lighting, an alternating current of 65 to 125 cycles per second is employed, the alternations thus being so rapid that the current is practically constant and no flickering is noticeable at the lamp. The winding of a magneto is, however, so simple that unless it be run at a very high rate of speed there is quite an appreciable interval between the recurrence of the cycles. Consequently a mechanical circuit-breaker actuated by the shaft of the magneto is employed. This maintains the armature short-circuited on itself, its opening being timed to coincide with the action of the make-and-break device in the cylinder, and also with the point of maximum value of the current curve, commonly called the peak. As the current curve, or wave, is of equal value at equal distances from the peak, this permits of advancing or retarding the time of ignition, though in practice there is found to be little need for this with low-tension ignition. In addition to synchronizing the action of the magneto with the running of the motor the use of a circuit-breaker, as described, also has another great advantage, in that the sudden opening of the armature circuit at the point of maximum current flow utilizes the self-induction of the winding to increase the value of the current, thus causing a much larger arc, or spark, at the point of rupture in the cylinder. The simple spark coil, with a single winding, is a familiar example of this action. If the magneto gear and the driving gear on your car, or whatever arrangement is employed, does not bear any distinguishing marks to facilitate timing the magneto, it may be done about as follows: Turn the motor over until the piston of the first cylinder is at the upper dead center, or what may be termed a medium-speed firing point. Remove the protecting plate from the armature of the magneto, unless its position can be determined otherwise, and turn the shaft by hand until the armature is in a position about 30 degrees from the horizontal; about one-fourth to one-third of the armature pole piece will then have emerged from the polar gap of the fields. As the point of maximum flux occurs when the armature is at approximately 45 degrees from the horizontal, this should provide ample latitude for advancing or retarding the spark. Mesh the driving gears in this position, marking them carefully for reference. Try starting the motor on the magneto and if the results be not as satisfactory as desired, changing the engagement of the gears one tooth forward or backward will frequently be found to make things right. The complaint that the magnets have weakened is an old standby of the repairman and should always be regarded suspiciously, unless the magneto has been permitted to stand with its armature withdrawn for some length of time. Such a charge can readily be refuted by turning the machine over by hand briskly and noting the spark.

**EXTREMELY HAZY AS TO TWO-CYCLE MOTOR.**

Editor THE AUTOMOBILE:

[1,026.]—Kindly answer these questions in the next issue.

1. Does a two-cycle engine travel twice as fast as a four-cycle, and if so, does it necessarily consume double the gasoline, batteries, etc., as a four-cycle one?
2. Will a two-cycle engine make 2,500 r.p.m., while a four-cycle but 500 r.p.m., and if so, does not this extra wear and tear offset the advantages of constant torque claimed for the two-cycle?
3. If the answer is yes to the second question, will not a two-cycle car travel twice as fast as a four-cycle?
4. Do you not think that the two-cycle superiority over the four-cycle type is only on paper?
5. Is not the Elmore the furthest advanced two-cycle car?
6. Is there any advantage in making six-cylinder, two-cycle cars over a four-cylinder one?
7. Can anything as to the balance of a motor be shown by the exhibition engines at the shows, which are run by electric motors?
8. Is not the Elmore the only two-cycle car licensed under the Selden patents?

FRIEND AND CRITIC.

1. No. A two-cycle engine cannot be made to run as fast under load as one of the four-cycle type, owing to the impossibility of getting a charge into the cylinder and out again at high speeds. This is one of the chief drawbacks of the two-cycle type.
2. The foregoing suffices to answer this question as well.
3. No. Two-cycle cars have never been noted for their unusually high speed.
4. Many of the claims of superiority made for the two-cycle motor are utterly unfounded, but they are not made by those who are aware of the relative merits of the two, and particularly not by makers of well-known two-cycle motors.
5. It is the only two-cycle car of its size that has been on the market for any length of time.
6. The gain would be merely theoretical and would doubtless be more than offset by the disadvantages of extra weight and mechanism.
7. No. The motor is only being run at a fraction of its normal speed under such conditions and is not under load.
8. Yes.

The nature of your queries shows such an utter lack of knowledge of the characteristics of either type of motor that it would be impossible for us to answer the first three without going to interminable lengths, and would advise you to read up on the subject in order to get a better understanding of it.

**CONCERNING THE DESIGN OF A SPRING WHEEL.**

Editor THE AUTOMOBILE:

[1,027.]—Kindly answer the following when convenient. In an autocar at rest (dead weight) and an autocar running at maximum speed, over the usual obstructions of country roads, what is the difference allowed by manufacturers for the extra pressure to be sustained by the wheels (the whole four wheels)? To illustrate, suppose a car to be 2,400 pounds in weight—we will not say anything about the extra weight of from one to five persons in this instance, but will consider that the 2,400 pounds at round figures covers everything. This will give each of the four wheels 600 pounds to carry or sustain when at rest—now what do you allow for the extra sudden weight that the four wheels in addition are called upon to sustain at the moment the reaction sets in, i.e., I mean when the full force of the weight falls upon the supporting wheels when running at the maximum rate of speed over obstructions such as offered by country roads? Would suspension or spring adjusted wheels rock, as I am working on, be required to be increased in strength to the extent of one-quarter, one-third, or one-half or more of the dead weight of said car, i.e., car weight (motor) 2,400 pounds; sustaining power of each resting wheel 600 pounds; sustaining power of each wheel in motion say to be one-half of the car's weight = 300 pounds per wheel = 900 pounds per wheel?

In conclusion, beg to say that I would be pleased to have you reply at an early date, if convenient, as I am about to place the order for my helical springs for the new wheels.

Easthampton, Mass.

CHARLES J. MALINGS.

A wheel that had no greater factor of safety than one which was merely designed to carry the weight of the car at rest, or 50 per cent. in excess, would be far from safe. In this, as in other forms of construction, the allowance generally made is several times that which calculations show the wheel will be called upon to stand in the course of ordinary service, and the

fact that the modern artillery wheel will frequently stand terrific shocks without damage, shows that its factor of safety is high. Just what the latter is, only the manufacturers of the wheels know, though there may be more or less data extant.

Lateral movement or side pressure, or, as you term it, "rocking," is one of the forces that nine spring wheel inventors out of ten totally overlook until they come to try out their devices. Such a wheel should have an even higher factor of safety than an artillery wheel, as it is not a solid construction, so that it should be capable of bearing several times the weight ordinarily imposed upon it, instead of 1-2 or 1-3 more, as you mention. A wheel capable of sustaining only 900 pounds, if placed on a 2,400-pound car and driven at speed, would provide a direct road to the hospital, if not something worse. As already mentioned, we are not aware of the percentage of the factor of safety of the ordinary artillery wheel, but would not be surprised to learn that one of these wheels could sustain 3,000 or 4,000 pounds without crushing, and probably more.

**WHAT IS THE CAUSE OF THIS FORMATION?**

Editor THE AUTOMOBILE:

[1,028.]—I desire to ask if you can give me any explanation of a condition which arose with my gasoline launch during the summer and which gave me a good deal of trouble.

I ran a 21-foot gasoline launch during the summer. This launch had a galvanized iron tank in the bow. My difficulty was that repeatedly the gasoline would not run out of the tank into the pipe leading from the tank to the engine. This I found to be occasioned by small flakes obstructing the outlet of the tank. These flakes were very thin, light yellow in color, varying in size from that of a pin head to that of a finger nail. They evidently formed in the tank, due to some peculiar action of the gasoline in the tank. These flakes would sink both in gasoline and in water, and seemed to re-form from time to time. When handled they would crumble into an almost impalpable powder. Have you had any similar experiences, and can you explain the formation of this material and how to obviate it?

Thanking you for your reply, either by letter or in "The Automobile," I am,  
EDWARD G. TUTTLE, M.D.  
New York City.

While we have never heard of a similar case, from your description of the flaky precipitate formed we should judge this to be the result of some chemical combination of the gasoline with the inside coating of the tank, unless the gasoline itself were of a very poor grade and would throw down such a precipitate, regardless of the nature of the container in which it was held. Galvanized iron tanks are seldom used on automobiles for holding gasoline, which probably accounts for the lack of similar cases. Doubtless the refiners could tell what the substance was and what is the cause of its formation. If any of our readers have ever had a similar experience we should be pleased to hear from them.

**SOME QUERIES CONCERNING VARIOUS MATTERS.**

Editor THE AUTOMOBILE:

[1,029.]—I have a few questions I would like to have you answer through "Letters Interesting and Instructive." (1) About what is the voltage of the spark as it takes place in the cylinder? (2) What should be the pressure of tires on a runabout? The tires are 28x3, the weight of the machine, 1,100. (3) Which is the cheapest in the end, and the most satisfactory, the magneto, dynamo, or batteries for ignition on a four-cycle, four-cylinder gasoline engine? (4) What should be put into a planetary transmission, oil, dope, or a mixture of oil and heavy grease. (5) I wish to put an oil tank with sight feed upon the dash and would like to know if it will drop by gravity into the crankcase, or will I have to have a pump to pump it in? The crankcase is enclosed and lubricated by the splash system.

LOWELL ELLIS.

Warren, Mass.

1. We believe it is estimated to be in excess of 100,000 volts, but to our knowledge no attempt has ever been made to accurately measure the voltage of secondary spark discharges. The potential required to bridge gaps of certain lengths in the air and in vacuo have been calculated, but the figures are not at hand.
2. Fifty pounds to the square inch.
3. We should say the magneto, but there is considerable op-

opportunity for a difference of opinion on the subject, as you may know.

4. Light machine oil, frequently renewed, will give the most satisfactory service. "Dope," or heavy oil and grease, will create too much friction between the pinions of a small planetary gear.

5. A gravity feed will work satisfactorily, but is not as reliable as a pressure or mechanical feed, in which the oil is forced through the tubes.

#### MR. RUSHMORE ON MR. LOUGHEED'S ARTICLE.

Editor THE AUTOMOBILE:

[1,030.]—The article on "Automobile Lamps and Their Lenses," by Victor Lougheed, in your December 12 issue, was read by us with a good deal of interest, and in the main is the clearest exposition of the optical principles of automobile lamps which we have seen in the trade publications. Two or three points, however, seem to require comment.

Mr. Lougheed seems to assume in preparing his diagrams that the intensity of the illumination is the same in all directions from an acetylene flame. In fact, this is far from being the case. Any luminous gas flame is more or less opaque to light rays passing through it, on account of the incandescent but solid particles of carbon which furnish the light. As the acetylene flame is particularly rich in these carbon particles, it is practically opaque, consequently the edges of the flame give an illumination substantially proportioned to their projected area, which, compared with the flat surface of the flame, is practically nothing. In other words, it is only the front and back of the flame that count, and the intermediate zone of the imaginary light sphere has little value. A short focus lens mirror, which catches nearly all of the rays from one surface of the flame, projects all the light that can in practice be utilized.

The opacity of the flame likewise defeats the theoretical argument in favor of the type of headlight which employs a parabolic reflector with bullseye lens in front of the flame and hemispherical cup behind the flame. As a matter of fact, even if the reflecting surfaces remained bright, which Mr. Lougheed very correctly points out is not the case, the flame would still stop the rear rays reflected back into it by the cup.

Finally, we will admit having some quarrel with Mr. Lougheed's use of the terms "project" and "efficiency." He shows in Fig. 6 the standard locomotive type of parabolic reflector, extending it, however, somewhat farther forward than is customary, and, after pointing out the deficiencies of any metal reflecting surface exposed to a flame, he states in the next breath that this reflector "projects" 88 per cent. of the light. As a matter of fact, it does nothing of the kind.

If the illumination were equal in all directions, it would intercept 88 per cent. of the rays; but it is one thing to intercept rays and quite another to project them. His use of the term "efficiency" is equally misleading. A steam boiler is rated at one horsepower for each 30 pounds of water evaporated per hour. If a certain boiler evaporated 3,000 pounds per hour and a 10-horsepower steam engine got away with all the steam the boiler could make, would Mr. Lougheed call the engine "efficient" simply because it took all of the steam? We hardly think so.

We ourselves used to make marine electric searchlights on the parabolic reflector-plus-lens-plus-hemispherical cup principle a good many years ago, before the lens mirror was heard of; and when we abandoned their manufacture, because shipmasters said, after a few weeks' service, they would not throw a beam the length of the ship, we were under the impression that they were not very "efficient," no matter how many rays of light were stopped by the reflectors.

Plainfield, N. J.

S. W. Rushmore.

#### WHY T. B. JEFFERY PROTESTED C. M. C. POINTS.

Editor THE AUTOMOBILE:

[1,031.]—In view of our having protested the decision of the technical committee making the awards in the recent 600-mile sealed bonnet reliability run of the Chicago Motor Club, we feel it only fair to state our reasons for such protest.

This run was undoubtedly the most severe official test of motor vehicles ever made, and, in the words of one of the judges, every effort was made to avoid perfect scores. In fact, these efforts were carried far beyond essential features, and though several cars made every control on time and finished in apparently perfect condition, with all seals intact, they were deprived of a final perfect score merely on account of inessentials or accessories.

In our own case the heaviest penalty, four points, was inflicted on account of a taillight, palpably broken by impact, and in all probability by another car while the contesting cars were being moved in or out of the official garage, as neither the observer nor the passenger in the rumble seat was aware of its being done, as

they undoubtedly would have been had the damage been done while the car was in service.

Under the circumstances, we felt it unfair to attach a stigma to our car on account of damage to an unimportant accessory from outside forces over which we had no control, and in which no weakness on the part of the car or accessory was even contributory.

We also protested the decision covering our primary or pedal brake.

In our judgment, based on several years' experience in automobile manufacture, it is inadvisable to so adjust this brake that by sudden or injudicious application the wheels may be locked and great and unnecessary damage be done to the tires. This brake is, however, in its present condition and adjustment sufficiently effective to stop the car within fifty feet with the car traveling at twenty miles per hour, at the instant of application, as was proven by several tests on various pavements. In fact, the judges admitted that the question was merely one of adjustment, and based the penalty of two points on the fact that but one minute or less would be required to adjust the brake to meet the requirements.

Should instant stop be required in case of emergency, so great that effect on tires is of no consideration, a second brake is provided that will instantly lock the wheels at any reasonable speed. We felt that as no notice to the contrary had been given, the matter of brake adjustment was within our discretion and protested the penalty, but the referee held to the contrary and sustained the decision of the judges.

We deeply regret the conditions that impelled us to enter protest against the judgment of the committee, and offer this statement only in order to acquaint the public with our position.

THOMAS B. JEFFERY & COMPANY,

Kenosha, Wis.

Thos. B. Jeffery.

#### MORE OF THOSE ACETYLENE EXPLOSIONS.

Editor THE AUTOMOBILE:

[1,032.]—While looking through "Letters Interesting and Instructive," of the November 14 issue of your valuable journal, I saw some accounts of persons having had explosions take place while bending or handling tubing for generator use. Would say that I have had the same kind of explosions in two distinct cases, one of them taking place directly under a leaking gasoline cock where the piping happened to be at that moment. The lamps on this car had not been in use for some three days, when we received orders to place the generator on the opposite side of the car. While bending the piping for same, slowly, a terrific explosion took place, and a red and bluish flame issued from the end of the brass pipe, the heat generated being so intense that my hands were severely burned. While bending another pipe on same car the very same kind of a noise was heard, this time without the bluish flame. This was a new experience for me, and am glad to see it so ably explained.

Toronto, Ont.

HARRY W. SPENCER.

#### IN DEFENSE OF PAINTED AUTO HEADLIGHTS.

Editor THE AUTOMOBILE:

[1,033.]—I saw in "The Automobile" of October 17 a letter by William Gray, criticizing people who do not use brass lamps. I think the painted brass and nickel lamps on a light painted car look best. I have had both. I find in my touring that not near as many horses are frightened at my car as it is now painted and has nickel lamps. I tour all over the country, and find it hard to get the brass cleaned, as it should be, by the men in the garages. It takes nearly an hour to clean the brass on a car as it should be done. I find now wherever I stop to stay over night the people come around my car and admire it very much, as it is odd. I think the time is not very far off when the brass will be removed by law, as the bright brass on an automobile coming suddenly on fine and high-spirited horses frightens them very much. This I am sure of, as I have tried both carefully. I am also a horseman.

Newburgh, N. Y.

E. D. W. ROSE.

#### STEARNS DID NOT HOLD RIVERSIDE RECORD.

Editor THE AUTOMOBILE:

[1,034.]—In your issue of December 12, page 877, under the heading "Riverside Annual Hill Climb a Success," I note in the first paragraph the statement: "The former record of 5:41 2-5, held by a six-cylinder Stearns, was lowered a fraction less than twenty seconds by a Stoddard-Dayton." This is a decided error, as none of our six-cylinder cars have ever been seen west of the Rocky Mountains to our positive knowledge; hence, it is impossible for any of our six-cylinder cars to have raced either at Riverside or anywhere else in California. Your Los Angeles correspondent was in error, and we trust that you will do us the justice of correcting this statement.

F. B. STEARNS COMPANY,

Henry H. Hower,

Assistant Advertising Manager.

Cleveland, Ohio.

## "IT COSTS MORE TO PRODUCE A SIX THAN A FOUR"

By F. B. STEARNS.

SOME time ago, knowing that there was a great deal of interest among automobilists in general concerning the relative merits of four and six-cylinder cars, I expressed my opinions on this subject in a general way, giving the views of our company on this proposition as a whole. Inasmuch as we are manufacturers of both four and six-cylinder machines we have nothing to gain or lose by the final decision of the public. We feel, however, that we are in a position to take an unprejudiced view of the subject, something which no maker of either fours or sixes exclusively can hope to do.

I was very much surprised to note the interest taken in my remarks by the automobile public in general and was extremely interested in the views expressed by other manufacturers. I was particularly struck by the attitude taken by two of the latter, both of whom presented the other view of the subject. One of these, who is a maker of both four and six-cylinder cars and is the pioneer builder of sixes in this country, set forth in a very interesting manner the arguments in favor of the six-cylinder. His views on the subject as a whole are manifestly fair and unprejudiced, and on this account we are more gratified at the compliment which he chose to pay our own six-cylinder in his remarks.

We can hardly say as much of the other maker, who is obviously heart and soul in favor of the six-cylinder proposition. His position in this matter is unique, as we understand that he is now making six-cylinders exclusively, something which no other manufacturer in the world has cared to do.

His article in reply to my remarks assumed apparently a direct attack by me on his product, than which nothing was further from my thoughts. Instead of refuting our general arguments in favor of the four by like arguments in favor of the six, he chose to dissect every statement and twist my meaning to suit his own ends. For example, in my former remarks I made the statement that a six was more difficult to time and had 50 per cent. more ignition apparatus than a four. His reply was as follows: "Fifty per cent. more ignition apparatus might be taken to mean that if four cylinders require one magneto six would require one and a half magnetos, and we assure an innocent and unsuspecting public that this fear has no foundation in fact."

We doubt if even a suspecting public would have so construed our meaning! That the ignition mechanism on a six is more elaborate than on a four is self-evident. That an ignition system that "would do" on a four is entirely inadequate for a six is further evidenced by the high-tension magneto system, finally supplied by the above maker of sixes in addition to the battery and coils.

The additional fractional part of a magneto is not required on a six, as our six-cylinder "spokesman" rightly informs us—a whole and complete system is required, however. What percentage of an ignition system is represented by a magneto can best be determined by "unsuspecting" purchasers of former models of this maker, whose cars lacked this part of the system. However, the need of a magneto for the six is by no means an argument against the six, for a well-designed four-cylinder motor is not considered complete without magneto ignition, although the magneto itself is somewhat simpler.

That the correct timing of a six-cylinder motor is more difficult than on a four is beyond question. If not, why the inevitable question of the buyer—"How does she fire?" Why the resulting confusion of the salesman?

The replies made to my arguments by other makers confined themselves mostly to the standard argument for the six—namely, flexibility and power. Unquestionably, flexibility and power compatible with simplicity and reliability is the ultimate aim of every

automobile designer. Flexibility and power are admitted advantages of the six-cylinder motor, but why to these should be sacrificed simplicity and reliability? Undoubtedly there will be one, two, three, six, eight and even twelve-cylinder motors made for motor cars, all with various arguments in their favor, but the four is and always will be the standard of the world for sane touring car practice. If flexibility is of any advantage at all, it is at its best in town use and through heavy traffic. Why, then, are all the town cars and taximeter cabs four-cylinders? Isn't it probable that the majority of these cars have attained the required flexibility by other means than the addition of two more cylinders?

Everything else being equal, carburetion is the one thing in a motor car which makes flexibility possible, and which makes the motor run equally well at high and low speeds.

Without a change in adjustment on our carbureter we have obtained a variation in speed of from 150 to 2,000 revolutions per minute with a four-cylinder motor, and with two more cylinders we have not been able to obtain the 50 per cent. greater flexibility. In fact, the variation in speed of the two motors is practically the same, and the proportion of the amount of power developed at the lowest speeds is not noticeably different. This difference in the action of the engine rapidly disappears as the motor speeds up, and we believe that with the engine running as low as 250 revolutions no difference can be noticed by the ordinary observer. With the usual reduction in gearing in automobiles as low a speed of the engine as this is never required, and we fail to see how any difference in the handling of the car could be noticed.

We believe that for a six-cylinder motor to be better than a four for automobile purposes its advantages should be apparent to the driver of the car at any and all times and at any and all speeds. Admittedly the six as a motor has its advantages. It also has its disadvantages, and we believe that these are far more apparent to the owner. For instance, a six will start harder than a four because of the additional friction. If this is not the case, why has one maker of sixes equipped his car with a self-starting device, which in itself is a complicated piece of mechanism? But this is of minor importance. Much more than this will the owner notice the strain on his pocketbook rather than on his arm. This strain comes from an increased first cost and an increased cost of maintenance, which always accompanies additional complications in any kind of machinery.

Invariably the price of six-cylinder machines is much greater than that of fours of equal power. If it does not cost more to produce these six-cylinder cars, why the added cost to the purchaser? It does cost more to produce a six than a four. It costs more because there are more parts, and if there are more parts there is more complication, and if there is more complication there is more trouble, and if there is more trouble there are more repair bills. We note from extensive advertising that an exclusive six-cylinder maker is probably anticipating this trouble, as he is offering large rewards "in gold" for good chauffeurs—a plan which, he says, "will benefit the owner."

We do not advocate saving money in the first cost of a car; we do advocate paying for quality rather than quantity. We know it is possible to obtain in a four-cylinder by proper design and workmanship the flexibility and power of a good six-cylinder.

We advise paying for right design and expert workmanship in the first place, which in the end will be more than paid for by a greater reduced cost of upkeep. It is our belief that this point of view is the correct one for the intelligent purchaser of any motor car. The idea that a new model, and in some cases a new type should be produced yearly, is radically wrong.

A maker of sixes to-day formerly made one cylinder, then twos, then fours and now sixes. The excuse given at each step was that the two corrected the faults of the one, and that the four overcame the difficulties of the two, and now the six is the best ever and corrects all the faults of his four. Where is this going to stop? So on *ad infinitum*?

This line of argument is all wrong. The field for one and two-cylinder motors is in cars of small power, and there are many such successful machines in use to-day. The field for the six is in cars of extreme power, and there are some of these in successful operation. But the four-cylinder remains as the standard of the world for an ideal powered car and a still further refinement of this type of car is the ultimate aim. There will be one and two-cylinders made, and sixes and even eights, but there is and will be but one standard—the four.

Let me emphasize what I said in my previous remarks—that a good four-cylinder car is good enough for anyone, and that there is no need to desert the four for the six. With a high-

class four under the hood it is impossible to detect it from a six at anything above an abnormally low speed. And for this one small advantage the purchaser must pay a higher price, must care for 50 per cent. more cylinders, have 50 per cent. more reciprocating parts, 50 per cent. more valves to grind, 50 per cent. more cylinders to clean out, 50 per cent. more ignition troubles, and if his motor ever goes wrong he has repair bills amounting to 50 per cent. more than if he had a four.

In continuing to build both fours and sixes, we have followed the example of such concerns as the Panhard, Renault, Mercedes, C. G. V., Fiat and many others of note.

Despite all statements and arguments to the contrary, the four-cylinder is and always will be the standard of the world, a fact which no amount of talk can overcome, for the simple reason that it is a fact. This is far from being an individual opinion, or the opinion of any one company, but is held by all the leading designers of the world, notably those mentioned above, in addition to the cream of the American manufacturers.

## "MAKER WHO HAS BUILT BOTH TYPES ABLE TO ARGUE"

By LOUIS GEYLER.

IN view of the fact that there are so many opinions on the subject of "fours" vs. "sixes," it is very evident that those manufacturers who are building four-cylinder cars and have no sixes to sell talk very strongly in favor of the fours, because they have to sell them. And those who are building sixes are naturally talking the other way. It is simply a question of whom the shoe fits. They all agree on one point, however, and that is that the *six has more flexibility than the four*.

It certainly stands to reason that the manufacturer who has built both types of motors is better able to argue the point than one who is only making a four. Although the Stevens-Duryea people do not believe in a large four-cylinder car—that is, a four-cylinder of 40 horsepower or over—they have built a new four-cylinder with a 4 3-4 bore by 4 1-2 stroke, which, according to the A. L. A. M. rating, gives them the same horsepower as their light six—viz., 36 1-10. This gives them two cars of the same horsepower, but they do not for one minute consider that their new four will do the same work as their light six. They certainly are in better position than any other manufacturer in the country to judge of this matter, on account of having two cars of practically the same horsepower in fours and sixes, and are in position to state which one they consider the superior. They are very emphatic in their belief that the six-cylinder car represents the acme of motor car enjoyment, and any person paying more than \$2,750 for a car should get a six. In other words, the stand they take is that the four-cylinder car they are building is as large a four as anyone should buy, which they consider the limit of horsepower, size and speed that should be embodied in a four. They are building this car to supply

the demand for a four-cylinder of moderate size and power, the same as some manufacturers are building two-cylinder cars to supply the demand for machinery of that particular class.

As everybody knows, the majority of foreign manufacturers are building six-cylinder cars in connection with their fours, and in the last five years the number of makers putting out six-cylinder cars has increased from one or two to over seventy. And in the last four American shows (including licensed and unlicensed) the steady increase of sixes is shown by the following table:

	1905	1906	Dec. and Jan. 1906-7	Oct. and Nov. 1907
Six-cylinders .....	2	5	18	46
Four-cylinders .....	127	256	333	258

Showing 46 six-cylinder models built by 28 different American manufacturers to-day, this does not tend to prove, as some people seem to think, that the six is a passing craze.

Just one more point before closing, which I believe will show the tendency stronger than all the technical arguments that can be brought to bear on the subject. This is, the Stevens-Duryea Company have sold and delivered up to the present writing 730 six-cylinder cars, both light sixes and big sixes, and they are being used from Portland, Me., to Portland, Ore., and from Minneapolis, Minn., to Mexico City, Mex., and they are all giving satisfaction. So far as I have been able to ascertain there is not one single man driving a Stevens-Duryea six who would go back to a four, except in case he wants an extra car as a runabout. The Stevens-Duryea Company is the only American company that has this number of sixes in use.

## PLEA FOR THE SIX-CYLINDER MOTOR ON "V" PRINCIPLE

Editor THE AUTOMOBILE:

There is nothing that is of more interest to the trade, and especially to the mechanical end of it, than the discussions of proper design that are now running in your columns. We all have at least one idea in common, that the future automobile must be reliable, powerful, and comfortable.

The chief discussion at present is concerning the power plant, and this is to be expected, for the fact that power plants differ more than any other detail signifies that the different builders are widely at variance as to what constitutes the best, from their point of view. One maker tells us that the "best" motor is the fastest one. The next one says his is better because more powerful; then comes the "smoothness" man, and the "durable," etc., etc. But I believe the majority purchaser will seek for reliability first of all, and this usually means few parts, and those few properly designed and well made from the stock best fitted for the purpose, which is not always the most expensive stock, either.

After being convinced as to reliability, my customer usually calls for power. He well says that he wants to ride faster up hill than down, because in case of accident there is much less trouble in calling a halt, and, while he may not care to make fast time very often, yet there are times when it is of the utmost importance that he arrive promptly. The matter of comfort is usually lost sight of, or at least largely, most people believing that any good car, as at present turned out, is not very hard on the passenger, so I am placing the matter of comfort at the tail end of the list, the other elements of reliability and power being so much more important.

So far as reliability goes, we are agreed that any motor may be reliably made, within certain limits, said limits being measured by weight of material, its distribution, and its speed and strain under service conditions. This matter of weight and distribution of material leads us to the discussion of the number of cylinders, and that means as between the "4" and the "6," for it is generally

conceded that while the single cylinder will do a certain amount of work well and will always be with us, and while the double opposed is extremely well adapted to many conditions and has an enormous future, yet the real, full-grown automobile will have either 4 or 6 cylinders, as more does not give proportionate advantage, and less does not give real results, either in power or use.

To my mind, the strong objection to the "6" as at present put on the market is its crank. No mechanic worthy of the name would think of transmitting power around so many corners as are found between the first cylinder and the transmission unless he was compelled to do so, and by this I mean that it is not good mechanics to do this, but it has to be done on the sixes as at present put out.

One of your able contributors, arguing against the six, said recently that he was unable to get 50 per cent. more power from six cylinders of the same size than he could get from the four, but I believe that if his test were made with the first four cylinders on a six-throw crank, he would find that he would not develop two-thirds as much power as with the full six, which is only another way of saying that, theoretically, the six will develop more power in proportion than the four, as the six certainly has 50 per cent. more displacement, and it certainly has not 50 per cent. more friction surfaces. So I believe the failure of the six to develop power in proportion is due more than any thing else to the utter impossibility of making a crankshaft that is stiff enough to carry the load developed in the front cylinders to the rear end, without large losses due to the bending and twisting strains on the shaft from one crank to the next, and so on to the rear end.

That a crank can be made that will do something in this place is indisputable, but that it can be made stiff enough to carry all the power of the front pistons is very doubtful, the peculiar shape of so long a crank tending to make it serve as a spring would if interposed between a hammer and nail. The further argument from the same source that a six calls for so long space that it

increases the wheelbase unduly, I do not agree with. No large car will give the best results under all conditions, either to its occupants or to itself, without a ten-foot wheelbase, and there is room enough here for the usual six, though it could be used for other purposes if not so occupied.

But the six is the smallest even number of cylinders that can be used in the 4-cycle plan, in which the impulses overlap, and hence it will surely run smoother, strain the transmission and tires less, and will always be in favor for these reasons. The "4" must always have two points in each revolution where nothing keeps it going but inertia, and then when the next power impulse arrives and takes hold suddenly, a strain is developed that tends to shorten the life of the material, and incidentally that of the occupants of the car. So that it seems to me that some form of the six is to be desired, if that form can be made more compact, and equally as efficient as the four is now made.

My suggestion in this connection is that we take a lesson from the very successful (if rather complicated) eights, that have shown more power for their weight than any thing else ever built, and set our six in two rows of three on a side, at 120 degrees, thus using a three-throw crank, dispensing with three bearings and their consequent friction, bringing the first three cylinders as near the work as the other three are, saving space, bringing our load lower and farther back if we wish to, and adding nothing at all in the way of complications, but rather decreasing them.

If this form is practical for an eight, it can certainly be adapted to the requirements of the six, and all users, as well as the makers, will be the gainers over any form now on the market. All the advantages of reliability possessed by the four should attend this design, and certainly in theory it should develop power in proportion to its displacement, while its easy qualities should be fully as good as the present six, if not better. I believe we shall hear more of this construction later.

Rutland, Vt.

W. L. ARCHER.

## "ALL IMPORTANT RACING EVENTS WON BY FOUR-CYLINDERS"

By J. D. MAXWELL.

THE controversy now on between the manufacturers of four-cylinder and six-cylinder cars is not new, nor is it one in which the Maxwell-Briscoe Motor Company has not had its say. As a matter of fact, our own experiments along these lines have antedated those conducted by many other manufacturers, and we have even overstepped the limits which the manufacturers of six-cylinder cars seem to have set themselves, for we have built and have now running, experimentally, eight-cylinder cars, and even one of twelve cylinders.

If we have returned to the making of two and four-cylinder cars, you will agree there must be good reasons for such course. As an example, let us remember that all important racing events have been won by four-cylinder cars. In the last Grand Prix there were two eight-cylinder English cars, one six-cylinder car made in Italy, and an eight-cylinder French car, but none of them gained honors in this contest, which was won by a four-cylinder car. All this, while not disputing the value of the six-cylinder idea, surely is pretty strong testimony in favor of the

efficiency of the four-cylinder type of the motor-driven vehicle. One phase of the dispute which seems to have been overlooked so far is that the final word will not be spoken by the automobile designer, but by the motorist, who, from all evidence, does not consider the six-cylinder car as past all experimentation. Both the four-cylinder and the six-cylinder have their relative advantages. It must be borne in mind that the automobile buyer of to-day is a rather remarkably well informed chap, who knows a good deal about motor cars, although he may never have owned one himself. The new type of purchaser, who only a few years ago was satisfied if his motor would take him over the roads in fairly good fashion, has become more fastidious—he knows what he wants and insists upon getting it. Nor can there be any question that he should get it, for it is he who pays the freight. And if you ask me why the 1908 Maxwell line includes no six-cylinder model, let me show you our orders for two and four-cylinder Maxwells and you have the answer.

## HOW TO ADVANCE THE SIX-CYLINDER INTERESTS

By CHARLES B. SHANKS.

THERE are two ways of advancing six-cylinder interest. One is a straightforward presentation of six-cylinder advantages by catalog, in the newspapers, and by salesmen. The second and the less expensive way is that of foolish opposition. Indeed we have found that the very absurdities urged against six-cylinders by advocates of the four have been extremely effective in convincing intelligent motorists that the six, lacking real, tangible defects for its opponents to pounce upon (as illustrated by their use of obviously illogical points), must be

a car well worth investigating. We hope our loving friends in the four camp will keep up their good work. They are doing quite as much to create a "six" stampede as are the "six" makers themselves.

A four-cylinder enthusiast says that six-cylinders are unnecessary. "Hark back to nature," he says, "and observe that the horse who has only four legs combines great speed and strength." On that basis the two-cylinder is still better, particularly for speed—did you ever see an ostrich run? What!

Next year's Tourist Trophy race on the Isle of Man will be run under four-cylinder, four-inch bore rules instead of the time-honored fuel limit regulations.

According to official statistics there were 1,672 cars registered in France in 1899. In 1903 the number had reached 12,984, and last year's registrations were 35,923.

ALL-WINTER UTILITY OF THE AUTOMOBILE AS EXEMPLIFIED ON NORTHERN NEW JERSEY'S FINE HIGHWAYS

## SOME AUTOMOBILE OBSERVATIONS THAT MAY BE OF HELP

By A. D. HARD, M.D., MARSHALL, MINN.

Bolts and nuts, screws and pins,  
Buy an auto and trouble begins.

**W**HEN the automobile fails to do its duty, the expert looks and thinks; the novice gets out all the wrenches and goes to work in an energetic manner.

Some operators use the throttle to control speed, and some use spark changer. The wise one uses both, with judgment.

A good anti-freeze solution for use in your acetylene generator in winter consists of one and one-half pounds of calcium chloride in one quart of soft water.

Too many monkey-wrench mechanics are serving as trained nurses in automobile hospitals.

If you can set your starting crank so that the first explosion will take place while you are pulling upward, there will be no serious results, even if there is a back-kick.

Equal parts of denatured alcohol and soft water make the very best anti-freeze mixture to use in a radiator. It will also answer to generate acetylene gas in your generator, however.

A small semicircular copper cup holding about one ounce, communicating with the inlet pipe about two inches from the cylinder by means of the 1-8-inch copper tubing used for gas lamps, makes the best priming arrangement for winter.

If you can put a 4-inch tire on a 3 1-2-inch rim you will save about 50 per cent. of your tire troubles.

## CLUBS OUTLINING NEXT SEASON'S WORK

### A. C. OF CINCINNATI GOOD ROADS CAMPAIGN.

CINCINNATI, Dec. 16.—The annual banquet of the Automobile Club of Cincinnati was held December 10 at the Business Men's Club, with State Highway Commissioner Sam Houston as the guest of honor. In his after-dinner talk Mr. Houston gave the members a history of road building in Chicago and made a stirring appeal for support in his efforts to get legislation by which the State will help build good public highways by paying one-half the expense thereof. He told of the status of the movements in other States, particularly commenting on the fact that Pennsylvania had appropriated a fund of \$4,000,000 to build State roadways.

Commissioner Houston said that in the past the principal opposition in the legislature to State aid in highway construction had come from two sources. First from members from the larger cities, who could not see why their constituents should bear the expense of road construction in the poorer counties of the State. The other source of opposition came from the members from the rural districts, who he said opposed the measure because they said that if they build good roads the city people would come out into the country with their automobiles and scare their horses off the road. At present Mr. Houston said the legislators from the city and those from the rural districts were beginning to realize more and more the advantage to both from good highways, and the prospects are beginning to be very bright that the two elements will give their united support to the movement. The appeal of Commissioner Houston for support brought the members of the club to their feet in a unanimous pledge to aid him in every way they can and on a larger basis than has ever before been attempted.

### PROGRESS OF THE ALBANY (N. Y.) AUTO CLUB.

ALBANY, N. Y., Dec. 16.—The membership of the Albany Automobile Club has increased during the past year from 70 to 168, and the officers intend to secure every automobile owner within a radius of twenty-five miles of Albany on its roll. During the past year the active work of the club has included attention to the various speed traps outside the city limits, many members and visitors having been saved from falling into the clutches of grafting constables.

Through the efforts of the counsel of the club, a precedent has been established by the courts that the maximum fine which can be imposed for a violation of the speed laws is \$50, and in case of arrest, if cash bail is given and a trial is desired, the amount of such bail cannot exceed the amount of the maximum fine, viz., \$50.

The club has on hand signboards to cover the route from Rensselaer to Pittsfield (a few of which have been erected), but, owing to proposed changes in the State road now in course of construction over a large part of this route, it has been deemed advisable by the committee having this in charge to wait until the routes are definitely determined before erecting the balance.

### NORTH JERSEY CLUB AFTER BAD CROSSINGS.

PATERSON, N. J., Dec. 16.—The North Jersey Automobile Club is making considerable progress in its efforts to have abolished or properly protected the dangerous railroad crossings in the vicinity of this city, as well as in other parts of the State when learned of by members of the club. A report will be filed shortly with the chairman of the New Jersey Railroad Commissioners and results are expected in the near future. There are some especially dangerous crossings near Paterson, and the club is using its greatest strength to have them abolished.

### LONG ISLANDERS READY FOR 1908 SEASON.

BROOKLYN, N. Y., Dec. 18.—With the election of officers on December 4, and the annual dinner two evenings later, the Long Island Automobile Club is now fairly well started on the season of 1908, which promises in every way to be a memorable one in the history of the organization. Charles Jerome Edwards, president; Dr. C. B. Parker, vice-president; Russell A. Field, secretary, and Louis T. Weiss, treasurer, bring to their new positions great hopes and enthusiasm for the future, and all possess the hearty endorsement and support of those who have figured in the early and later successes of the club. Activity and a business-like administration will be the watchwords.

No definite announcement of the plans for the ensuing year has as yet been made. It is certain, however, that there will be no let-up in the fight for better road conditions and rational legislation. The bill for the extension of Eastern Parkway through Cypress Hills Cemetery to Forest Park, which would provide some means of decent communication between Brooklyn and other parts of Long Island, will be pushed as never before. This most important measure all but passed both branches of the State legislature this year.

C. J. EDWARDS, President. DR. C. B. PARKER, Vice-President. LOUIS T. WEISS, Treasurer. R. A. FIELD, Secretary.

One of the features of the annual dinner was the presentation of the trophies offered for competition in various events this year. A brief summary of these trophies follows:

Trophy offered by James Edward Bristol for the member making the greatest mileage during the regular touring season: Won by Charles Jerome Edwards. Distance 10,202 miles. Cadillac car.

Trophy offered by Willard P. Reid for the member touring in the greatest number of States: Won by Samuel H. Burns. Seventeen States and the Dominion of Canada. Packard car.

Trophy offered by Wm. Payson Richardson for the L. I. A. C. man recruiting the greatest number of new members for the year: Won by Louis T. Weiss. Thirteen members.

Trophy offered by Wm. Payson Richardson for member attending the greatest number of regularly organized club runs: Won by Leffert Lefferts.

Despite repeated efforts, the contest committee found it impossible to decide the ties resulting from the endurance run held over Long Island roads, and the trophies thus offered will remain in the custody of the club after the names of the cars in the ties are engraved upon them.

### SPRING ENDURANCE RUNS OF PENNSY CLUBS.

YORK, PA., Dec. 16.—Spurred on by the success of other endurance runs held recently in the Keystone State, local auto-ists are planning for a two-day run next spring, which will take in Lancaster, Philadelphia, Reading and Harrisburg. A southern route was suggested, but the trip through the State seems the

most popular one. According to the plans, the first day's run will take in Wrightsville, Columbia, Lancaster, Coatesville and Philadelphia. The night control will be at the Quaker City, thus making the mileage about 100 miles. Two routes have been suggested for the second or final day's run, but the one most generally spoken of takes in Reading, Harrisburg, Middletown and Columbia. It has also been suggested that the second day's run be via Reading and Lancaster to this city. Between 125 and 150 miles will be covered the second day. No date has been set, but the run will probably be held the latter part of May. This will enable the York autoists to participate in the annual run of the Motor Club of Harrisburg, which is to be held earlier in the spring.

#### BALTIMORE'S CLUB TO TRY SPEEDY MEMBER.

BALTIMORE, Md., Dec. 16.—The board of governors of the Automobile Club of Maryland will sit as a court of investigation when one of the members, Frank Brown, Jr., son of ex-Governor Frank Brown, of Maryland, and the present Democratic leader of Baltimore city, will be tried on charges of reckless speeding of his automobile, which resulted in the death of a pedestrian on one of the principal streets of the city, Thanksgiving morning. Brown has already been fined \$25 and costs by a police magistrate on the charge of exceeding the speed limit and was censured by the grand jury, which, in a special report, condemned Brown's action as brutal and cowardly, but claimed that no presentment could be found against him on the evidence produced, which was insufficient to hold him on.

Since last March the club has been committed to a policy of co-operation with the authorities in the punishment of violators of the speed ordinance. If Brown is found guilty of recklessness he will be liable to a suspension of not less than thirty days or for such longer term as the board in its discretion shall determine, according to the nature of the evidence.

Other matters under consideration by the club are the prevention of "joy" riding by chauffeurs, securing a new country and city home, and efforts, in co-operation with the American Automobile Association, to secure a Federal system of registration and identification. The club has received numerous complaints of the loose methods of garages in allowing chauffeurs to take out and return cars any time of the day or night without making note of the same, as well as inadequate provision for verifying the amounts of gasoline used each month. The Philadelphia method of keeping a record of the departure and return of machines, whether taken out by the owner or chauffeur, and the forwarding of memos of the supply of gasoline to owners daily are favored and will likely be adopted.

#### BAY STATERS HAVE ANNUAL BANQUET.

BOSTON, Dec. 16.—About one hundred members of the Bay State Automobile Association attended the annual banquet of the organization, held Tuesday evening of last week at the Hotel Somerset. President L. R. Speare was unable to be present, and in his place J. C. Kerrison, of the board of directors, presided. The speechmaking was informal, among those called upon being James T. Sullivan, of Boston; George W. McNear, of the Bay State house committee; President John P. Coughlin, of the Worcester Automobile Club; ex-President S. L. Haynes, and Harry Fisk, of the Automobile Club of Springfield; William Noon, and others. The Bay State association is in excellent condition and is preparing for an active season during 1908. The association will look carefully after the interests of autoists at the State House this winter and next spring will enter into outdoor sports with its usual enthusiasm.

#### WASHINGTON CLUB'S CONTEST HELPED SALES.

WASHINGTON, D. C., Dec. 16.—The spacious clubhouse of the Automobile Club of Washington was thronged with automobilists on the evening of December 10, the occasion being a smoker

given in honor of the drivers and observers in the sealed bonnet contest held that day. President Caverly and the house committee arranged a very attractive program, and in addition all the drivers who finished with clean scores were called upon to say something about their experiences on the 118-mile journey over Maryland roads. The contest served a very good purpose in awakening renewed interest in automobiles and members of the trade are making sales every day as a direct result of it.

#### AUTOMOBILE CLUB OF AMERICA LADIES' DAY.

NEW YORK, Dec. 17.—At the A. C. A. clubhouse, on West Fifty-fourth street, this afternoon was designated as "Ladies' Day," the fair sex having the privileges of the clubhouse and being served with light refreshments. A substantial attendance was the result.

In the evening the entertainment committee provided an illustrated lecture by O. P. Austin, Chief of the Bureau of Statistics, Department of Commerce and Labor, the subject, "Curious Transportation Methods in Queer Corners of the Earth," being most interestingly presented by the speaker.

The usual dinner for members preceded the lecture. Orrel A. Parker, chairman of the entertainment committee, is receiving much commendation for his energetic efforts.

#### AUTO CLUB OF KANSAS CITY PROSPEROUS.

KANSAS CITY, Mo., Dec. 14.—The Automobile Club of Kansas City now has a membership of 174 and a balance in its treasury of \$1,980.53. During the past year it has conducted many successful events, including a race meet, an orphans' day, as well as giving pleasure rides to the inmates of other charitable institutions, and various club runs. The annual banquet of the club in January will be a good roads affair, and President William H. Hotchkiss, of the American Automobile Association, is being prevailed upon to be one of the principal speakers. The club is a member of the Missouri State body of the A. A. A.

#### A TEXAS AUTO CLUB WHICH IS DOING THINGS.

DALLAS, TEX., Dec. 14.—The Dallas Automobile Club, at its recent meeting, elected thirteen new members, giving it a total of 77 out of 150 registered owners in the city. The meeting decided to bring influence to bear upon the congressmen of the district in favor of the federal registration law being put forward by the Legislative Board of the American Automobile Association. The club will appoint members to look after the streets and roads of the city, and efforts will also be made to assist the local officials in enforcing the sane use of automobiles in Dallas.

#### JERSEY'S BIG CLUB TO DISCUSS PRESENT LAW.

NEWARK, N. J., Dec. 16.—There will be a special meeting of the New Jersey Automobile and Motor Club on Thursday evening for the purpose of discussing such amendments to the present automobile law as may be deemed necessary. The legislative committee of the club has been looking into the matter very carefully and is only waiting the sanction of the members to endeavor to complete its work. The club, being a member of the Associated Automobile Clubs of New Jersey, will endeavor to secure the co-operation of the State body, the officers of which have not been particularly energetic of late.

#### PHOENIX, ARIZ., FORMING AUTOMOBILE CLUB.

PHOENIX, ARIZ., Dec. 12.—The automobile owners of Phoenix, Ariz., are going to have a club. At the recent meeting, Thomas Armstrong, Jr., was selected as temporary chairman and Arthur Ainsworth as secretary, and G. P. Bullard, R. B. Burmister, and Judge Ainsworth as a committee to draft a constitution and by-laws. All automobile owners in Phoenix will be invited to be present at the next session.

EARLY WINTER AUTOMOBILING HAS A CHARM THAT IS EQUALED BY NO OTHER OPEN AIR PASTIME.

### TO TEST DOUBLE REGISTRATION IN INDIANA.

INDIANAPOLIS, IND., Dec. 16.—Through the efforts of automobile dealers, manufacturers, and concerns employing automobiles in their business, a test case has finally been started to determine the validity of the city automobile license ordinance. At a meeting held at the garage of the Fisher Automobile Co., practically every automobile concern in the city, as well as a number of owners, were represented. It was decided to take the suggestion of city officials and test the ordinance. When a number of cases were called in police court that of Charles T. Austin was selected as the one upon which to base the test. He was fined \$1 and costs, and bond was immediately given for an appeal to the circuit court. If Austin is held guilty by the Circuit Court, the case will be carried to the Indiana Supreme or Appellate Court. A sufficient sum of money has been pledged to bear all costs.

The city license ordinance was in effect several years before the State automobile law, which requires \$1 registration fee and expressly prohibits any municipality for exercising any ordinance conflicting with the law. The city license fee is \$3 yearly, and not more than one-half of the owners in the city have paid it this year.

### NON-RESIDENTS HAVE TEN DAYS IN DELAWARE.

WILMINGTON, DEL., Dec. 16.—The new automobile law, which goes into effect in Delaware, January 1, is the same as the existing law, except that it allows non-residents the privilege of being in the State for ten days without taking out a license; terminates all licenses on December 31 of each year; places the

age limit for chauffeurs at 16 years; places dealers and manufacturers in a special class, making one license good for several cars; prohibits loaning, licensing, or using unregistered cars, and provides a fine up to \$100 or imprisonment up to 30 days upon an intoxicated person operating a car.

### AUTOWAY FROM LAKEWOOD TO QUAKERTOWN.

ASBURY PARK, N. J., Dec. 16.—Good news for automobilists is contained in the announcement that in Lakewood a movement is on foot to build a road from Lakewood which will connect that New Jersey winter resort directly with Philadelphia. The project bids fair to go through, and when it does autoists will have one of the finest and straightest speedways in this part of the country. Philadelphians will find it as easy to run up to Lakewood as to go to Atlantic City. It will also make another route for New York automobilists in their runs to the Quaker City. It is given out that George Gould, John Hays Hammond, and William Hamilton are the backers of the project at the Lakewood end, while the Philadelphia contingent is also representative. Work has begun on the Lakewood end. It will be a turnpike wide enough for three cars to run abreast, and all such arrangements as drainage, culverts, and fences will be carefully worked out. A sufficient number of toll-keepers will be installed and paid by the autoists to keep the road in good condition. The highway will run from Lakewood through Lakehurst, New Egypt, and so on direct across New Jersey, to the Camden ferries. If the work is pushed as fast as is now planned, the road will be ready early next year.

## CONCERNING THE OVERHEATING OF AUTO ENGINES

By H. H. FRANKLIN.

**M**ANY people have entirely wrong ideas on the subject of overheating an automobile engine. As everybody knows, power is obtained in a gasoline motor by turning the gasoline into heat. Hence the motor which utilizes the largest percentage of the heat in the gasoline is the most economical.

Lubrication determines the degree of heat at which a motor can be safely run. The hotter you can run your engine, and still lubricate, the greater efficiency you can get out of your gasoline. Cylinder oil "flashes" or burns at about 450 degrees. So long as the inside of the cylinder is kept below that temperature the pistons can be properly lubricated.

In a water-cooled motor the working temperature is determined by the steaming point of water. Water boils at 212 degrees; it steams freely at 200 degrees. Hence a water-cooled motor cannot run above 200 degrees, because at that point the water evaporates

so rapidly that it is soon lost. As soon as the water is gone the empty water-jackets hold the heat, instead of allowing it to radiate. Then the temperature quickly runs above the burning point of oil and the pistons stick.

The Franklin air-cooled motor works with the outside of the cylinder walls at a temperature of about 350 degrees. This means that the inside is hot enough to get good efficiency out of the gasoline, and it is still far enough below the "flashing" point of oil to give a big margin of safety.

The water-cooled motor running at about 200 degrees obtains less power from the gasoline consumed than an air-cooled motor, like the Franklin, running at 350 degrees. The hotter the motor, the greater its efficiency. On the other hand, the water-cooled motor goes out of business at about 30 degrees, because then the water freezes and something bursts.

**Influence of the Parts Maker on Auto Design.** Though the subject is dwelt upon from time to time in the automobile press, the importance of the rôle carried out by the manufacturer of parts seldom seems to be appreciated at anything like its real value. It may be for the reason that the majority of automobile builders do not like to admit that Doe's gearboxes and Roe's steering gears enter into the make-up of their productions, not to mention rear axles of another make, and frames, brakes, or any one of a half dozen other components that might be cited. Such an admission might be considered as a tacit avowal of the fact that the maker in question was really nothing more or less than an assembler, instead of a builder of automobiles—and all wish to have the latter reputation.

However, it is practically an impossibility to draw a definite line of demarcation where assembling ends and building begins. It is generally admitted that the use of a stock motor marks the assembler, but after passing that point there are innumerable parts of the car which are purchased from special makers by even the largest builders. Nothing short of a catalogue would suffice to include a complete list of such parts, and credit for the great improvement in their design and construction during the past few years is certainly due, in the great majority of instances, to the parts maker. Two years ago, when the flanged mud-guard first made its appearance, the observer was considerably struck by the unanimity with which leading makers had adopted it—overnight, as it were. That such a number of widely separated makers had conceived and carried out an idea of this

kind simultaneously seemed more than a coincidence and investigation proved this supposition to be unfounded. Here, as on many other parts of the car, particularly such as the gearbox and steering gear, it was merely an illustration of the influence of the parts maker on the design of a large number of makes.

**Development of Speed and Distance-Recorders.** Among the many things that the automobile has brought in its train few have been carried to such a state of development in the same length of time as is the case with what has come to be familiarly known as the "speedometer," through the fact that this was the trade name given his product by a pioneer maker of these instruments. Distance covered appeared to be the only information desired by the cyclist regarding his travels, so that similar attachments designed for the two-wheeler never got beyond that stage, and it remained for the automobile to be responsible for the production of this entirely new type of instrument. Numerous makers have entered the field, and a correspondingly diverse number of instruments has been the result, but with few exceptions all seem to have carried their special systems to a high standard of efficiency and accuracy.

In the course of a few years these instruments have become so universally introduced as now to form an almost indispensable part of the car. The exhilaration of speed is made doubly alluring by definite knowledge of the rate attained, and this indisputable evidence forms the foundation of endless tales of drives at a high pace. With such inducements as this, coupled with season and trip mileage figures, on one hand, and the stern necessity of keeping within the absolute letter of the law in so many places, on the other, it is not strange that the demand for speed and distance indicators has grown to such amazing proportions during the few years that they have been on the market. At first their use was confined to a very large extent to the high-powered cars, on which even the cost of the highest-priced instruments formed but a negligible fraction of the cost of the car itself, and it was an early fad to have the dash ornamented with as much as could possibly be put on it. For that matter, the question of price has served to restrict the use of the speedometer, more or less, to cars selling above a certain price-limit, but within the past two years more extended experience in the manufacture of these instruments, as well as greatly improved facilities for turning them out, have served to bring them within the reach of even the small car owner, so that there is very little doubt that within comparatively few years their use will be universal.

**Extreme Case of Obeying the Law to the Letter.** Nothing is better calculated to bring about reform in traffic speed regulations than a rigorous application of existing laws. A New Jersey automobilist who, like many others, had chafed under the speed restraining regulations of more or less authoritative bodies, relates how he was brought to see the error of his ways and penitently resolved at all times and under all circumstances to maintain the exact legal rate of speed. At the same time there was born within him a love for driving on the street car tracks. When half a dozen trolley car drivers found they had to follow in a ten-mile-an-hour procession because of an automobile on the tracks, aid was demanded of the police, only to find that there was no law compelling other users of the roads to keep off the tracks, and that to ask the automobilist to go faster for the convenience of the trolley cars was more than could be expected of a policeman. Further, on looking up the matter, it was discovered that the franchise of the street railroad company limited the trolley cars to a lower rate of speed than that accorded later to automobiles. As to the wisdom of the policy of the New Jersey driver even automobilists are likely to be divided; its legality, however, is beyond question. As an object lesson it is effective—too effective probably, for it visits the iniquities of the guilty upon good and bad alike.

## WHAT IS BEING DONE ON THE LONG ISLAND MOTOR PARKWAY

**A** LARGELY attended meeting of the board of directors of the Long Island Motor Parkway, Inc., was held in the general offices of the company, 527 Fifth avenue, New York, at 11 o'clock Thursday, December 12, with W. K. Vanderbilt, Jr., presiding.

The president reported at length regarding the activities of the various committees, the chief engineer, the general manager, and the treasurer, and submitted reports and blueprints indicating that thirty-four miles of right of way between the Jericho Turnpike, at Mineola; Fulton street, in Hempstead Village, and Garden City on the west and Lake Ronkonkoma on the east, had been secured, that detailed surveys had been completed, applications made to the various boards of supervisors, highway commissioners, etc., for their consent to cross the various high-

ways between these points, either above or below grade, and that the engineering department was now preparing detailed tracings for these various crossings, including the three crossings of the Long Island Railroad at Mineola, Central Park, and in Hempstead.

The chief engineer reported on various types of road construction which he was investigating, and on which tests were now being made. The chief engineer and the general manager further reported that the right of way between Riverhead town and Riverhead village had been surveyed in full, and that the Riverhead Board of Trade had worked most enthusiastically in furtherance of the project. Reports were made showing that the rights of way between Lake Ronkonkoma and Riverhead town were being secured.

## LOOKS LIKE A STOCK CHASSIS RACE AT SAVANNAH IN MARCH

**S**AVANNAH, GA., Dec. 16.—The *Savannah News* in a lengthy article printed yesterday tells of the visit of representatives of the American Automobile Association who came to Savannah at the invitation of the Savannah Automobile Club and the civic and trade bodies of the city, the trip here being for the purpose of investigating the claims of Savannah as the place for holding one or more long-distance road races. Frank G. Webb, vice-chairman of the A. A. A. Racing Board, who served as the designated substitute of Chairman Jefferson de Mont Thompson; N. H. Van Sicklen, chairman of the Technical Board, and Frederick H. Elliott, secretary of the national organization, composed the visiting trio.

Mayor Tiedeman, County Commissioners Albert Wyly and A. B. Moore; President Williamson, of the Chamber of Commerce; President Wright Hunter, of the Cotton Exchange; President

W. B. Stillwell, of the Board of Trade; President F. C. Battey, of the Savannah Automobile Club; Chairman R. J. Davant, of the City Council, and Harvey Granger and J. J. Rauers, prominent members of the Automobile Club, escorted the visitors.

The *News* story contains the following: "The three men were sent to Savannah by President Hotchkiss of the A. A. A. to look over the course and see what the prospects were for the holding of the national stock car meet on the local course in March.

"As has been held all along by the men handling the local end, the course appears to be the best of its kind on this side of the Atlantic and it is for that reason that the A. A. A. have sent its most representative members to personally investigate. They are more than pleased."

A final conference was held to-day and this afternoon the visitors left for the North.

## HOW THE FAMOUS AIRSHIP "PATRIE" WAS LOST TO FRANCE

**P**ARIS, Dec. 10.—The primary cause of the loss of the French military airship *Patrie* was the breakdown of the ignition system through the mechanic's jacket catching in the distribution gears. The airship was over Toul, and but two miles of accomplishing its journey of 150 miles from Paris to Verdun, when the mechanic allowed his loose jacket to engage in the gears. The Panhard engine was fitted with double ignition, but as distribution was from the same shaft, the accident put both out of business. It would have been easy to descend and drag the ship to its shed, but in the spirit of *amour propre* the pilot decided to repair the damage and enter under his own power. All night the airship was held by 800 troopers, and next morning moved to a more sheltered position, secured by anchors and held by soldiers. There appears to have been negligence in not

attaching the valve cord to a bag of ballast, for on the second squall, when the airship was torn away from the troops, it was impossible to find it among the mass of cordage. Thus the *Patrie* rose into the air with its envelope fully inflated and no means of the gas being liberated automatically.

Henry Deutsch de la Meurthe's *Ville de Paris*, offered by its owner to the war authorities, has been accepted by General Picquart and will enter into service immediately. The *Lebaudy*, practically a sister ship of the *Patrie*, has been ordered to be put into commission also. Four other ships of the *Patrie* type are also projected, one of them, the *Republique*, being ready for delivery in March, and the *Democratie*, *Justice* and *Vérité* to be started as soon as funds are devoted by Parliament. The value of the lost *Patrie* is declared to be \$60,000.

## NEW YORK AUTO TRADE MAY HAVE SPRING OUTDOOR SHOW

**I**N order to present something in the way of an exhibition at a time when automobile buying is at its height, the dealers of New York City, as represented by the New York Automobile Trade Association, will probably hold a show when the spring season opens. In accordance with a suggestion made at the last meeting of the association, at its headquarters in the Motor Mart, Sixty-second street and Broadway, last week, this

is to take the form of an open-air affair combined with a race meet, having for its venue the old Morris Park race track. As the betting ring under the huge grand stand is capable of accommodating as many cars as Madison Square Garden, this location is considerably favored, and Secretary Stratton, of the association, has been instructed to ascertain the feeling of the trade in the matter and see what arrangements could be made.

### WORCESTER CLUB HAS MANY EX-MAYORS.

WORCESTER, MASS., Dec. 16.—The Worcester Automobile Club had the second smoker of its season Tuesday night, when Alfred Thomas, of the board of governors, told the members of his experience in England and the Continent last summer in his Pierce Great Arrow touring car. He told of motoring conditions in England, France, Belgium and elsewhere, and besides giving general conditions told of personal experiences. He covered 3,500 miles abroad.

Election returns were likewise given at the smoker, for it was city election day. James Logan was elected Mayor, but the leading feature of the election was the majority of 962 for no license. Worcester will, after May 1, 1908, when the licenses now in existence will expire, be the largest "dry" town in the country. This will effect the Worcester Automobile Club in common with all other clubs in the city, and the board of governors will soon meet to decide on the policy which will be followed in the café department, owing to the changed conditions after May 1.

Mayor John T. Duggan, ex-officio an honorary member of the club, whose term of office will expire January 6, has announced his intention to become an active member. In this he follows the example of his predecessors, ex-Mayors Edward F. Fletcher and Walter H. Blodgett.

### MORE CLUBS FOR MICHIGAN STATE BODY.

GRAND RAPIDS, MICH., Dec. 16.—J. R. Jackson, chairman of the membership committee of the Michigan State Automobile Association, has just formed a club in Hart consisting of 25 charter members, which, of course, becomes a member of the State body. The officers are: President, Dr. L. P. Mulder; vice-president, J. D. S. Hansen; secretary, J. D. McClellan; treasurer, Carl F. Flood. Besides the officers, the board of governors will consist of J. W. Nicholson, John S. Fisher and Rupert Steele.

Mr. Jackson is working with the Muskegon autoists and expects soon to have an association formed in that city, which has a rapidly growing colony of automobile owners.

### CANADIANS AND "CHAUFFEUR'S RAKE-OFF."

TORONTO, ONT., Dec. 16.—The nuisance known as the "chauffeur's rake-off" has become so pronounced in Canada of late that the Ontario Motor League has taken steps to prevent it, by organizing a chauffeurs' bureau in connection with the League. The purpose of the bureau is to protect owners of cars who employ chauffeurs from unscrupulous practices on the part of their drivers. Numerous complaints have been made that chauffeurs exact, or try to exact, a commission from dealers on supplies purchased from them for their employers. Cases have been known where this having been refused, the chauffeur has induced his employer to take his car to another garage.

The chauffeurs' bureau will undertake to investigate, on request of members of the Ontario Motor League, the record and character of any chauffeur who may apply for employment. It will also keep a register of competent and reliable chauffeurs who are looking for employment, and place them in touch with owners needing drivers. Details of the organization are being worked out at the secretary's office in Toronto.

### PHILADELPHIANS TO HAVE NOTABLE BANQUET.

PHILADELPHIA, Dec. 16.—At the last meeting of the Automobile Club of Philadelphia, the good work being done by the Automobile Club of Delaware County was recognized by an appropriation of \$100 to assist the hard-working suburbanites in their good roads campaign. Twice that amount was placed at the disposal of the sign committee, which is engaged in marking all the principal routes leading into this city.

The preliminaries for the annual banquet of the Philadelphians were planned at the meeting, and efforts will be made to secure the presence of Governor Stuart, Highway Commissioner Hunter, and many national and local automobile celebrities. The banquet is one of great importance socially, and is always noted for its well-known guests of honor.

Last Saturday's blizzard put an effectual quietus on the club's second "legal speed limit run," scheduled for that day, and it was indefinitely postponed.

CONTESTANTS IN THE RECENT SEALED BONNET CONTEST OF THE AUTOMOBILE CLUB OF WASHINGTON HALTING EN ROUTE.

CONSISTENT adherence to a well-outlined plan of chassis has marked the De Luxe car, built by the De Luxe Motor Car Company, Detroit, Mich., ever since it has been on the market, and in presenting its model for 1908, the company calls attention to a number of small changes which may be most aptly classified under the category represented by the now time-honored term "detailed refinements," as none of them is a departure from previous standards in any sense of the word. Chief among these changes has been the adoption of internal expanding and external contracting metal to metal brakes, of the shoe type, centered on the driving wheels, in place of the brakes formerly located on either side of the transmission. A dual system of ignition has replaced the battery and coil outfit of last year, the Eisemann high-tension magneto having been adopted for the working side of the system, while the standard, four-unit coil type, with low-tension timer is relied upon for emergency purposes. Tire sizes have also been increased, 4 and 5-inch front and rear sizes replacing the 3 1-2 front and 4 1-2-inch rear used last year, while riding has been made still easier by the use of Lemoine three-point suspension rear springs, instead of the individual semi-elliptic springs formerly a feature. The clutch has likewise been improved by the abandonment of the plain leather-faced type, in favor of a metal to metal cone provided with cork inserts, which makes disengaging much easier, beside extending the efficient life of this essential of the car considerably.

With the exception of the improved oiling system, this suffices to sum up the

PLAN VIEW OF CHASSIS, 1908 CAR DE LUXE.

changes made. Where the latter is concerned, a continuous circulating system has been introduced to maintain the crankcase supply of oil at a constant level at all times. This consists of an auxiliary oil tank, placed directly beneath the crankcase proper, and from which a pump, operated by the camshaft, serves to raise the oil to the crankcase. The oil-pan of the latter is provided with overflow stand pipes, the outlets of which are placed at exactly the level desired to be maintained, so that all excess oil finds its way back to the tank by gravity, and is again pumped up, or circulated. In addition to this provision, a six-tube, mechanical force-feed oiler having sight-feeds on the dash, is provided. Four of the feed tubes are taken to the cylinders, one to the pump bearing and one to the timing gears, from which it will be evident that two independent systems of lubrication are, in reality, employed, and the first is one that is greatly appreciated by the average driver as it entirely eliminates any question of the height of the oil in the crankcase, whether the car has been driven 100 or 1,000 miles. The only attention required by such a system is a periodical flushing out and replenishment of the oil supply, as the latter loses its lubricating properties after long service.

So far as the remainder of the motor is concerned, it is distinguished by all those features of design and construction that have been identified with the De Luxe car in former models. The cylinder dimensions are 5-inch bore by 5 1-4-inch stroke, while the horsepower rating is 50. Both the inlet and exhaust valves are located in the cylinder-

THE DOUBLE REAR AXLE DRIVING AND SUPPORTING MEMBERS.

heads, and are inclined at an angle of 20 degrees to the vertical, which makes it possible to give both of them a diameter equivalent to half that of the cylinder itself. They are operated by double-contact rocker arms, one push rod and rocker arm serving to operate each pair of valves, so that the engine is particularly simple in this respect. These rocker arms are chrome

nickel-steel forgings and are supported on yoke-topped, adjustable pillars, one end of the arm resting on the top of the exhaust valve stem, while part of the other end acts as the contact for the intake valve end and the second part is hooked to the push rod. This, accordingly, necessitates the use of but four push rods and four cams. In addition to the adjustable supporting pillar, further provision is made for timing the valves by giving the push rods adjustable connections at their upper ends. Another advantage of

SHOWING BEVEL GEAR DRIVE.

this construction is that any of the valves may be removed without disturbing their timing adjustments. Instead of relying entirely upon the ground fit employed on the intake-valve cages last year, this has been supplemented by a sleeve nut which holds the intake valve cage to its seat in the cylinder head, making an absolutely tight joint.

The crankshaft is a one-piece, chrome nickel-steel forging of high tensile strength, supported on three unusually liberal-sized D. W. F. ball bearings. It is customary with the makers of the latter bearings only to guarantee them when they are

TYPE OF BRAKES, DRIVE SHAFT AND BALL-BEARING OF WHEEL.

of the size required and have been installed in accordance with the recommendations of their own engineers, but in the De Luxe the designers have specified a size larger than those called for by the bearing makers. As is the case with the motor, practically every essential of the car has been designed exclusively for it. This will be particularly evident in the case of the rear axle, which is of a double type, upon which patents have been granted. As will be seen from the accompanying illustration of it, the entire weight is carried on the solid, one-piece, chrome nickel-steel axle of I-beam type, very much resembling a typical forward axle with its downward sweep, which is to allow for the differential and drive housing, as well as to permit of accurate alignment of the driving shafts. The second half of the axle is really not an axle at all, but is simply the driving mechanism, which has no part whatever in carrying the weight of the vehicle. The driving shafts have squared ends fitting the differential pinions, and extending through the outboard tubular ends of the I-beam supporting axle, where they engage the hubs of the driving wheels by means of a special clutch device of substantial size which is forged integral with the shaft. The details of the

MOTOR DE LUXE FROM THE CARBURETER AND VALVE SIDE.

bevel gear drive are also shown in one of the accompanying illustrations, and this essential, like practically every part of the car, is supported throughout on ball bearings. Six of the D. W. F. imported annular type are used here alone, while five are employed in the gear-set, four in the steering-gear construction, six in the driving axles, one in the clutch and eight on the wheels, making a total of 33, counting those on the crankshaft. As already mentioned, the brakes are now centered on the driving wheels, where they are located in large steel drums. They are of the internal expanding and external contracting type, and both are equally effective in either direction, the former constituting the running brake and being operated by pedal, while the latter is the emergency and is controlled by the hand lever. A very simple equalizing device insures an evenly distributed contact on each of the brake drums. Both brakes are lined with special friction surfaces consisting of a special composition of bronze, which are adapted to be easily replaced at a nominal expense, when worn.

One standard type of chassis will be built, but several models are listed, including a roadster, which sells at the same price as the touring car, \$5,000, a limousine and landaulet being listed at \$6,250. respectively.

## NEXT THE IMPORTERS AT MADISON SQUARE GARDEN

WHEN cackling hens, cooing pigeons and quacking ducks have been noisily turned out of Madison Square Garden next Saturday night, a new staff will rush in to fit the building for the Importers' Automobile Salon, a goodly share of which is now being brought from Europe on various liners. On Saturday, December 28, America will be given her first look at the products of French, German, Italian, English and Belgian factories for the 1908 season, and allowed to gaze until 11 o'clock on the following Saturday night.

A complete transformation of the Garden is promised for what the promoters have entitled the "Paris Salon Transplanted," the decorative scheme to be unique, artistic and altogether *chic*. The interval of six days between the departure of the roosters and the arrival of the Europeans would not be sufficient to install the decorative work had not all the preliminaries been pushed ahead for the past two or three weeks at the decorators' own shops. Thus everything is expected to be in readiness for the opening hour.

A full list of the exhibitors, together with the cars that will be shown on the main floor of the Garden, is as follows:

Auto Import Co. (Rochet-Schnelder); Archer & Co. (Hotchkiss); Brewster & Co. (Imported cars); S. B. Bowman Auto Co. (Clement-

Bayard); C. G. V. Import Co. (C. G. V.); Darracq Motor Car Co. (Darracq); Delahaye & Pflain Import Co. (Pflain-Delahaye); De Dietrich Import Co. (De Dietrich); Fiat Automobile Co. (Fiat); Itala Import Co. (Itala); Isotta Import Co. (Isotta-Fraschini); Martini Import Co. (Martini); L. P. MacNamara (Renault); Maja Co., Ltd., Am. Br. (Maja); Percy Owen (Blanchi); Panhard & Levassor (Panhard); Palais de l'Automobile (Delaunay-Belleville); J. M. Quinby & Co. (Imported cars); Rothschild & Co. (Imported cars); Rolls-Royce Import Co. (Rolls-Royce); Renault Frères Selling Branch (Renault).

A list of the tire, accessory and publishing concerns which will occupy the elevated platform and mezzanine floor, subject to a few possible changes at a later date, is as follows:

H. T. Alexander Co.; American Chauffeur; Acetyvone Co.; Automobile Topics; Auto Supply Co.; Robert Bosch; S. F. Bowser & Co.; Continental Caoutchouc Co.; Class Journal Co.; Central Automobile Top Co.; Cole & Woop; Comptoir d'Innovations Pour Autos; Dow Tire Co.; Diamond Rubber Co.; Fisk Rubber Co.; B. F. Goodrich Co.; Glaenger & Co.; Healey Leather Tire Co.; Hartford Suspension Co.; Hartford Rubber Works Co.; Isaac G. Johnson & Co.; Leon Mann Co.; Lavalette & Co.; Motor; Charles E. Miller; Michelin Tire Co.; National Sales Corporation; N. Y. & N. J. Lubricant Co.; Pneu l'Electric Co.; Pennsylvania Rubber Co.; Leon Rubay; Spare Motor Wheel Co.; S. Smith & Son; Samson Leather Tire Co.; C. E. Splittdorf; Victor Shock Absorber Co.; Warner Instrument Co.; Wood Mfg. Co.

## DETROIT WOULD HAVE CONTINUED EXCEPT FOR ST. LOUIS

DETROIT, MICH., Dec. 14.—Unqualified success crowned the first annual show of the Detroit Automobile Dealers' Association, which closed to-night at Riverview Park. In point of attendance all expectations were exceeded, while a careful canvass of those exhibiting brings forth the statement that the aggregate amount of business done was better than at any previous show held in Detroit. Not all this was real money. Many sales were made outright, and others booked. But possibly the most encouraging feature was the number of inquiries and the interest shown by live "prospects."

Several dealers went into the show with fear and trembling, feeling that with the financial flurry still fresh in mind and the holiday season at hand there was little to hope for. That they

were disappointed—and agreeably, too—in the outcome is a matter of record.

So enthusiastic were the dealers and so marked the interest of the public that the question of continuing the show for another week was freely discussed. Had it not been for the fact that a number of the exhibits were going to St. Louis, the show would have been continued. As it is, with this season's success in mind there is every probability of next year's show lasting a fortnight.

To the efforts of Chairman Alex. I. McLeod and Manager E. LeRoy Pelletier can be attributed much of the success achieved, although they were backed up by the Detroit Automobile Dealers' Association at every turn.

## ST. LOUIS SHOW OPENS WITH MOST OF AMERICA'S FINEST

ST. LOUIS, Dec. 16.—Again are the sleek show beauties—the shining representatives of the leading American makers—on exhibition, this time on the banks of the Mississippi. Rushed to Detroit from Chicago, they have made another quick jump here, and a small army of attendants were set to work transferring the contents of the special train to the exhibition spaces in the big Jai Alai building on Friday, where a second division undertook the renovation of the toilets of the many much-exhibited cars, which had lost more or less of their pristine brightness during the many miles of railroad travel they have had since the beginning of the show season. The show is the second annual event held under the auspices of the St. Louis Automobile Deal-

ers' Association, and is being well managed by D. M. Strauss. What with the large number of complete exhibits brought on from the national show and the unusually good showing made by the local dealers, this year's affair far eclipses its predecessor, and this is also true where the decorations are concerned, the management having spared no pains to make these in keeping with the importance of the occasion. The show opened Saturday night and the attendance was excellent. St. Louis forms an exception to the general run of automobile show cities and keeps open house for the public on Sundays, which is really one of the big days here. Another one this year will be "society night," which will be Tuesday, when the admission will be raised to one dollar.

### PENNSYLVANIA 1908 LICENSE TAGS ARE OUT.

PHILADELPHIA, Dec. 16.—The first of the 1908 Pennsylvania license tags was issued from the offices of the State Highway Department at Harrisburg last Thursday. They have a yellow ground with black lettering. Over two thousand applications have already been filed for them.

### RACING DRIVER TO HANDLE WAR AUTO.

PARIS, Dec. 11.—A Panhard automobile fitted with a Hotchkiss quick-firing gun has been sent to Oran to be used against the rebellious tribesmen. Captain Genty, head of the army automobile corps at Vincennes, will be in charge; the captain has competed in a number of races under the name of De la Touloubre.

HOBENICHT IN HIS POPE-HARTFORD THAT TRIED FOR RECORD.

### LOST RECORD IN SIGHT OF GOAL.

SAN FRANCISCO, Dec. 10.—Another attempt was made recently to lower the record made by Fernando Nelson, in his 40-horse-power Columbia, between San Francisco and Los Angeles. The start was made December 3 at 10:30 P.M. by Rudolph Hobenicht, in his Pope-Hartford touring car. Hobenicht had with him Jack Fleming, who has made quite a reputation as a driver. As the record was made with four passengers aboard, Hobenicht had to carry two others, who were James Fleming and Ernest Alford. At the appointed time R. R. l'Hommedieu gave the word and the car shot down Guirero street and out the Mission road to the country. It was a wild ride all night at every point. Hobenicht was ahead of Nelson's record. Everything went along smoothly until after Santa Maria had been passed and the car was nearing Los Olivos, while Hobenicht was at the wheel. Suddenly the forward left wheel dropped into a rut and away went the spring. There was no chance to make repairs until Santa Barbara was reached. They shouted to a party in one of the towns through which they were passing to 'phone to Santa Barbara and tell those there of their trouble. A short time after the engine practically stopped from overheating. An examination was made and it was found that the petcock on the radiator had unscrewed, an accident heretofore unknown. They had to wait until the engine cooled before they could proceed, which cost them over an hour. Where the stop was there was not a tree or shrub in sight from which could be cut a plug to stop up the radiator. Fleming stuffed it up with his handkerchief, which was only a makeshift affair and leaked so badly that they had to stop time and again to take water. Finally Santa Barbara was reached. There they met "Bill" Reuss, of Los Angeles, who took the wheel.

Then began one of the wildest rides in the history of the game on the coast. Reuss opened up the car to the limit and just let her go. Through two of the hardest mountain passes the car flew at a frightful pace. It was just after getting through the first pass that in making a sharp turn the tires on the front wheels were torn off and the temporary repairs to the broken spring lost. The tires were put on, and the wild ride resumed with the car resting on the front axle. There was never a let-up on the pace, and the car was brought into Los Angeles ahead of time. It was just after getting within the city limits that the car had to cross a railroad track. The pace was too fast and the front wheels turned at right angles to the car and the next second it was hopelessly ditched. The car went over with a crash and the four fell clear of the machine and luckily escaped without the slightest injury. At the time of the accident it was only five blocks from the finishing line with eighteen minutes to the good. The fact that the record was practically broken has caused Homer Boushey, the head of the house which handles the Pope cars in San Francisco, to decide to make the attempt again.

### THE OPTIMISM OF THE SALES MANAGERS.

F. C. Gilbert, Sales Manager for Pope-Toledo: "It is wonderful what can be accomplished by thought rightly directed. The great success of the Chicago Automobile Show was a grand demonstration of 'thought-power.' The managers of the show were determined to have everyone come in the right-thought attitude, to boost, and the result was splendid. Everybody I met was happy. I have long been a student of 'thought rightly directed' as a great factor in a sales campaign. When the power of thought is understood and properly used we will reach the zenith in commercialism; no panics, no great failures; all will be harmony. Each man will get his share of success, because when we become sufficiently enlightened to live by and work by 'thought-power,' our present jealousies and strifes will become as nothingness. The tendency of the times is toward the development of this heretofore latent force. The outlook is very good."

R. M. Owen, General Sales Agent for Reo and Premier: "It was very gratifying to me to learn of the hopeful attitude which our dealers exhibited at the Chicago Show. This was notably true of our agents in the West and South. That this optimism on the part of our agents is genuine is shown in the fact that our November and December deliveries have been much larger than in any previous year. This is probably due somewhat to the earlier shows. Be that as it may, it is nevertheless true that conservative business and professional men throughout the country have not in the least abated their interest in the economy, efficiency, convenience, and many other advantages afforded by the high grade, moderate-priced, simple, reliable and durable power-driven vehicle. The 1908 outlook is very encouraging with us."

E. C. Corder, Studebaker Branch, New York City: "While we have had a steady demand for enclosed cars, and have made a number of sales, we had not anticipated much retail demand for touring cars at this season of the year, and have been most agreeably surprised at the interest taken in this type of car and the number of sales made. In spite of the alleged stringency in the money market, the outlook, as far as we are concerned, is certainly most pleasing."

### FRANKLIN MOTOR COMPLETES ITS TEST.

CHICAGO, Dec. 16.—On the closing day of the show here there was brought to a successful termination the strenuous test of a Franklin air-cooled motor that had been undertaken by the local branch to demonstrate its cooling powers under adverse conditions.

During its continuous, seven-day run the motor made a non-stop record of 168 hours, its performance being the equivalent of a distance of 3,500 miles. The gasoline consumption was 40 miles to the gallon, and the lubricating oil but one gallon for each 300 miles. At 12:30 P.M. on the last day the motor was stopped long enough to replace the muffler, and was then immediately restarted and the car taken out on the street, where it was driven about steadily until 10:30 that evening.

### CLAIMS FINEST GARAGE IN COUNTRY.

PHILADELPHIA, Dec. 16.—To-morrow there will be opened by the Keystone Motor Car Company its new concrete garage and salesrooms at 216-220 North Broad street, said to be the finest building of its kind in this country. Fifty-three feet wide by 200 feet in depth and four stories high, it is fitted up with every possible convenience, not alone for the comfort of its patrons, but for the quick transaction of the company's business. The salesroom, which extends across the entire Broad street front, is two stories in height, the handsomely ornamented ceiling being studded with numberless electric lights, while the tessellated floor is strewn with handsome rugs. The Keystone concern handles the Packard and Buick.

SUCCESS AUTO BUGGY FOR 1908—FOUR HORSEPOWER.

### PIONEER AUTO-BUGGY CONSTRUCTORS.

Though he has been building automobiles ever since 1896, when by dint of a great deal of labor and much perseverance he succeeded in installing as light a stationary engine as was procurable, beneath an express wagon, and made it run, John C. Higdon, of St. Louis, who is the president of the Success Auto Buggy Manufacturing Company of that city, has always been a firm believer in the future of the buggyabout type and has never devoted his attention to any other form of construction. Quite in contrast with the ton or more of engine which he was compelled to utilize on his first car, is the neat little engine which characterizes the 4-horsepower Success Auto-Buggy of 1908. It is of the single-cylinder, inclosed flywheel type and is attached to one end of a special angle-iron frame extending clear across the body. The motor drives to a countershaft carrying a planetary change-speed gear through a chain and sprockets, and from this another chain drive is taken to a second countershaft, forward of the first. This second countershaft extends outboard on the left-hand side and its alignment with the rear axle is maintained by a distance rod, the final drive being by a third chain and only the wheel on that side of the vehicle being driven, thus dispensing with a differential. This machine sells for \$250, and not a few of them are in use in the West.

The company also lists a much more ambitious model for 1908, in the shape of the 10-horsepower Success Auto-Buggy, which is fitted with a double-opposed, four-cycle, air-cooled motor, the builders also giving the option of a 12-horsepower water-cooled motor of the same type at a slight extra charge. Both cars have the regular buggy running gear and body, with wheel steer, and with the exception of the power plant and double-chain drive of the latter the specifications are practically the same. The 10-horsepower model lists at \$400.

### TITUS MAKES 24-HOUR TEST ON THOMAS CAR.

NEWARK, N. J., Dec. 16.—Five hundred and twelve miles through snow, rain and slush, have been covered by Fred Titus and John Prowett with a Thomas touring car, in their self-imposed twenty-four hour touring test. The two men and their car from Buffalo made a double run round a circuit comprising Princeton, Trenton, Camden, Atlantic City, Toms River, Lakewood, Freehold and New Jersey, the roads being a fair sample of the good and the bad of the State. In the cars with them were George Walters, official observer, and E. E. Pearce, his assistant. During the run the engine was not stopped and no adjustments were made other than the replacing of two punctured tires. With the exception of the last breakfast, all meals were taken while the car was running, the exception being enforced owing to the exhaustion of the provisions on board. Tests were made by the occupants of the car of various kinds of clothing, but neither leather, rubber, furs, nor felt were able to keep out the cold and the wet.

### THAT STARTLING NEW YORK TO I

Seven cars are declared by *Le Matin* to be... 'round-the-world tour which it is organizing in conjunction with the *New York Times*. How the run will be made, what route will be chosen, and what the details of the contest will be neither journal is yet able to announce definitely. The *Matin* declares emphatically that towards the end of February the competitors will leave Paris, travel to Calais, cross the English Channel, run up to Liverpool, then embark for New York, where the difficult part of the trip will commence. Four routes are projected for crossing the United States, but the organizers stop when the region of the Bering straits is reached and has not much advice to offer on the best way of getting across Asia.

Marquis de Dion, who had two cars in the Pekin-Paris event, has written to the *Matin* very wisely asking that more time should be granted manufacturers to prepare for the long and dangerous journey. Two months in which to make arrangements for the supply of stores and fuel along the route and for the construction of special cars is manifestly not sufficient. Speaking on the type of car he would use in the tour, the head of the De Dion Bouton firm declares that he will employ a 30-40-horsepower engine capable of driving the car at a speed of thirty miles an hour, but geared to run as low as three miles an hour where necessary. Road wheels will be of sufficient size to give ample clearance in any kind of country and will be equipped with pneumatic tires capable of being dismounted and replaced by wooden rims in the Arctic regions. Four spare air-cooled cylinders will be carried along on each car to replace the water-cooled ones when the coldest regions are reached. A heating apparatus will be fitted to warm up the engine sufficiently to start. At the forward end of the car will be mounted a windlass operated by the motor, by means of which the most difficult portions of the road can be negotiated. Provision for the driver will be secured by means of a leather tent over the body, so arranged as to make the car habitable when it is necessary to camp out.

Two American firms—Hol-Tan and Franklin—which have promised to take part in the run to Paris have not yet announced any detailed plan of action, and, so far as can be learned, have taken no steps for the construction or fitting out of their cars. If the start really is to take place from Times Square, New York City, in March, there is no room for delay. The wiser plan would appear to be to wait until such arrangements can be made to assure the success of the daring enterprise. As the Bering straits can only be crossed in winter, delay beyond March would mean a postponement until the following year.

### NATIONAL DEALERS' ASSOCIATION ORGANIZED.

CHICAGO, Dec. 16.—As the result of several meetings held during the course of the show here the organization of an association to promote the interests of those connected with the automobile and supply business was effected. It is known as the National Retail Dealers' Automobile Association, and was launched with a charter membership of thirty, with good prospects of doubling this number within the next few months, as the annual dues are but \$2. The officers are: President, C. F. Jensen, of the Steinhart-Jensen Automobile Company, Joliet, Ill.; vice-president, R. Hokanson, Hokanson Auto Company, Madison, Wis.; secretary, J. A. Crum, Krueger Auto Company, Oshkosh, Wis.; treasurer, L. Ohnhaus, Ohnhaus Auto Company, Fort Wayne, Ind. The officers were made members of the board of directors ex-officio, which is comprised of the following three members in addition: Mr. Tanberg, Tanberg Auto Company, La Crosse, Wis.; Mr. Sutter, Sutter & Gamble, Burlington, Ia.; and Don P. McClure, Oskaloosa, Ia. The president appointed a committee of two, consisting of L. Ohnhaus, Fort Wayne, Ind., and N. A. Carlsen, Butte, Mont., to act in conjunction with him in the drafting of by-laws for the association. The next annual meeting is to take place in connection with the 1908 Chicago show.

## BRIEF ITEMS OF NEWS AND TRADE MISCELLANY

A 1908 Franklin touring car of 16 horsepower gave an interesting hill-climbing demonstration at Wilmington, Del., a few days ago, ascending Third street hill, about a 45 per cent. grade, covered with rough cobblestones.

Mrs. Myra E. Roach, of Milwaukee, Wis., claims the distinction of being the only lady driver in the United States to have driven a two-cylinder car over 20,000 miles in three consecutive seasons. Mrs. Roach, who employs a Rambler, drove 8,000 miles the first season, 6,000 the second year, and the same distance in 1907.

The Philadelphia Ford Motor Club recently held the first of a series of winter social gatherings, when two-score members with their wives, husbands, brothers, and sisters, journeyed to Woodbury, N. J., to the home of one of the members. The Fordites of Philadelphia are growing, and at the present rate should reach the century mark before another year rolls round.

The Fort Pitt Motor Mfg. Co., New Kensington, Pa., makers of the Pittsburgh "Six," expects to have its first car ready within the next two weeks. Two models will be manufactured, one a six-cylinder runabout with disappearing seat, selling at \$1,850, and the other a six-cylinder touring car, selling at \$2,250. George Von Rottweiler, general manager of the company, has just completed a trip to the eastern cities in the interests of the new car.

Announcement has been made from the plant of the York Motor Car Company, York, Pa., that a new runabout product, to be known as the 4-40 runabout, or gentlemen's roadster, will be put on the market about the first of the new year. Plans of the new car were submitted to the western agents at the recent Chicago show and many orders taken. Sales Manager H. R. Averill put in a busy week at the Chicago show and established a number of new western agencies. During the past few weeks three carloads of Pullman touring cars were shipped to San Francisco.

An incident depicting the cheerful kindness that has been born of the successful opposition of the automobile to the horse-drawn vehicle was witnessed during the recent days of slippery streets in New York. At the direction of the officers, the street in front of the Rainier Company's place, on Broadway at Fiftieth street, was kept strewn with ashes for the benefit of the suffering horses. The Rainier cars and others running past were having no trouble, and in a business way there was "nothing in it" for this concern to help along the horse, so it was a piece of magnanimity very becoming to a company of such substantial standing.

A recent story in a newspaper of Bangkok, Siam, goes to prove that "naturc faking" is not an exclusive American institution. The story in question relates how an attack was made on an automobile by one of two white elephants which were being driven to the river for their morning bath. This elephant is credited with seeing in the automobile, which was a Rambler car owned and driven by C. G. Edwards, of Bangkok, a strong competitor in the transportation business, and to have been imbued with the idea of accom-

plishing its destruction before it could breed any more of its kind in the land of Siam. Mr. Edwards' car came through the encounter with only a lamp and mud-guard broken.

In the \$5,000 advertising contest, conducted by Arbuckle Bros., the coffee importers of New York, the first prize of \$2,000 was won by Charles W. Mears, of the Winton Motor Carriage Company's advertising department. There were 18 prizes and hundreds of contestants. The purpose of the contest was to secure new ideas for the advertising and sale of Ariosa coffee, and the Winton man put the best suggestions over the plate. He advised against freak schemes, and strongly advocated the persistent use of daily papers. Mr. Mears has been associated with the Winton company for four years as assistant to Charles B. Shanks, the general sales manager, and one of the cleverest men in the automobile industry.

R. W. Daniels and a party of friends in a 40-horsepower Studebaker last week made a test trip from New York City to Boston and return. In talking over the journey, Mr. Daniels said: "Everything went along in apple-pie order. We had a most satisfactory trip, the motor working like a charm, and we had no trouble the entire distance. Some rain storms crossed our path at the start, thus making the roads very slippery and muddy. In one place we were all but hub deep in the mud. Despite this, however, we managed to complete the journey in nine hours, and were congratulated upon our fine showing when we arrived in Boston. The return trip was made in perfect weather, and was much enjoyed by the party."

Two rules which should always be kept in mind by automobilists desirous of reducing their tire expenses to a minimum are, says the Michelin Tire Company, to keep the car fitted with tires large enough to carry the load easily and to always keep them well inflated. Michelin tires, when new, will stand a test of over 300 pounds to the inch. If not sufficiently inflated there will be excessive friction between the plies of fabric and rubber, resulting in the wrecking of the tire prematurely. If the tire is well inflated there is reduced deformation under load; reduced deforming means reduced action between the plies, less friction, less heat, and longer life. There is very little danger of getting tires inflated too tightly. A 3-inch Michelin, when new, will stand a strain of not less than 800 pounds to the square inch; 4 1-2-inch tires will stand 50 per cent. more. It is difficult with any means at the disposal of the automobilist, to inflate tires to more than 100 pounds to the square inch. Drop the pressure to 40, 30, or 20 pounds and more tires will be used up in a 50-mile run than would be consumed in 500 miles under proper conditions.

Not being satisfied that the two weeks' test carried out during the course of the New York show conclusively proved how long the Atwater-Kent Spark Generator would run on a single set of dry cells, the makers, the Atwater-Kent Manufacturing Company, Philadelphia, Pa., transferred the entire outfit, consisting of the set of cells, the spark generator, Jones' speedometer, electric

motor and the glass case containing them to the Chicago show. As the result of its two weeks' running the odometer showed a record of 4,249.6 miles, while the batteries, which had showed an average of 6 amperes at the conclusion of the first part of the test, had deteriorated to the extent of showing but 4 1-2 at Chicago. The outfit was officially restarted, exactly where it had left off, barring the loss in the cells, and when it had run 5,328.6 miles the plugs began to miss for the first time. On publicly breaking the seals and testing the battery, the cells were found to show an average of 3 amperes, thus losing but 1 1-2 amperes in a 1,000-mile run, a fact which strikingly indicates the extremely small current consumption of the spark generator. The latter was found to be in perfect condition at the end of its long run and all the plugs sparked regularly when fresh cells were inserted. The contact adjustment was not changed throughout the test.

### NEW AGENCIES ESTABLISHED.

Edwin Kilburn, of Spring Valley, Minn., has closed a contract to handle the Ford line of automobiles in his district next season.

From January 1 the present agency in Chicago for the Thomas-Detroit will be changed. It is intended either to place a direct agency or open a branch. Coey & Company will continue to handle the Thomas Flyer.

Twenty-eight new agencies in thirteen States have been placed by the Forest City Motor Car Company, of Massillon, O., makers of the Jewel automobile. In addition three agencies have been concluded for abroad, in London, England, Cuba, and Porto Rico.

### PERSONAL TRADE MENTION.

W. N. Norton, the newly-appointed superintendent of the Autocar Company, has been officially installed in his new position at the factory in Ardmore, Pa.

C. S. Ransom, for the past two years general manager of the Albany Garage Company, Albany, N. Y., has severed his connection with that company and taken up the agency for the Stevens-Duryea car at 5 Tweddle Building, Albany.

### THE WORK OF THE COURTS.

A judgment for \$19,195 has been entered by default against the Christie Direct Action Motor Car Company, formerly of 519 East Eighteenth street, New York City, in favor of William Gould Brokaw for the amount now due on a demand note of the company dated April 13, 1907, payable to the Christie Iron Works, which indorsed the note and delivered it to Mr. Brokaw. When the note was made Walter Christie was president of the company and Harry H. Tredwell treasurer. The company was incorporated with a capital stock of \$300,000.

Judge Wheeler, of the Superior Court, has granted permission to the receivers of the Pope Manufacturing Company, Hartford, Conn., to continue manufacturing four months from December 28.

## Auto Law in Paris

FRANCE in general, and Paris in particular, may properly enough be considered the stream and fountain-head of the life of the automobile world of to-day, and for this reason it will be interesting to know what one may not do, and what are some of the restrictions which bear most heavily upon the automobilist, be he a Frenchman or a mere tourist. It's quite a novel point of view at any rate.

**THE OCTROI.**—There are those folk in the United States that curse the tariff tax, but surely no such onerous tax is levied upon the comings and goings of a free people as that of the Octroi at Paris, which takes account of the gasoline and oil in the tanks of your automobile as you pass the fortifications, and makes you pay accordingly.

At each of the fifteen or more *grandes portes* leading through the Paris ramparts, whether one arrives by the Côte de Suresnes and the Porte Maillot, or Meaux and the Porte de Vincennes, an octroi official, clad in the dingy uniform of French officialdom, steps out from his hut and demands that you declare the amount of *essence à pétrole* and *huile* in your reservoirs. Of course you don't know exactly, having been touring outside of Paris for days and weeks and filling up as occasion required, and you say so frankly. You might have said ten, fifteen, or forty liters, as many frequent comers and goers do, and take the chances, and if you said it convincingly the statement would be accepted; otherwise, as in the present case, you would tumble your cushions and all your paraphernalia about while the hard-worked (*sic*) official takes the exterior measurements of your tanks and prods a dirty stick down the bung-hole and marks the remaining depth of gasoline thereon—literally a measurement by rule of thumb. Outrageous, isn't it? So think the Parisians themselves. *Quel faire?* One must live (*"il faut manger,"* the Frenchman always replies to any animadversions cast upon officialdom), and if all the octroi officials in France were suddenly bereft of their jobs by the abolishment of octroi dues they would fill the almshouses, or else would have to emigrate, as have the Basques and the Alsacians. Bureaucracy is a good thing in overcrowded Old World countries; it takes care of a lot of the drifting population who would otherwise compete with others of more brain power, but a bureaucracy that clogs the wheels of progress is a doubtful blessing.

Gasoline sells for a very high price within the gates of Paris, and you may not bring a supply with you for your own personal needs of the next fifteen minutes, in order to arrive *chez vous* without paying your little contribution to the city. Obviously, you don't buy essence (gasoline) in town either, at least not more

than you can help, enough to take you through the gates and allow you to draw up outside before a dealer's, where they sell you the same article at 35, 36, 37, or 38 sous the liter instead of 50 or 55 inside the walls. This is

a tax which works out at from 40 to 60 per cent., and for one who goes in and out of the city much it mounts up alarmingly.

The revenue of the city of Paris from this one source alone must be enormous, and it is a growing one day by day. In the last three years the automobiles passing through the Porte de Chatillon alone have increased from six thousand per year to ten thousand, and these numbers are probably exceeded by those of the Porte Maillot, and perhaps others of the encircling group. And all to accomplish what? The collection of a revenue: yes, by the driving outside the walls a trading in gasoline and oil (and uncounted volumes of attendant and necessary small purchases which must run yearly into millions of francs). *Tant pis pour Paris alors!*

The crime is a grave one if you attempt to sneak by the octroi barrier, or make a misstatement—and expensive. It is less expensive if you have unwittingly run by the half-hidden shack the octroi authorities all over France designate as a *bureau*, and have been called back and made to show your *papiers*. You can make excuses till the cows come home, or the carbide in your lamps runs out, and you may state as emphatically as possible to the *gendarme* who now enters the *mêlée*, and all the rest of loitering officialdom, that you didn't know, that you are an *étranger* anyway, and don't live in Paris nor in effete old Europe at all, but it will make no difference. Everybody is formal, polite and good-natured, and you can but feel that they believe all you say, and that they don't call you down because they hate you but because they have the authority. They are not vindictive or *méchants*, these representatives of the law in France, but the *procès-verbal* will cost you something just the same—and the object is only to prove that yours was not a wilful case of disobedience, but only a case of ignorance of the law, for which you pay in France as elsewhere, though perhaps not for the same reasons. The bill of costs will be something like the following: Amende, fos. 10; Assignation, 10; Frais de Justice, 11.50; Frais d'Extraits, 1.25; Timbre, .25—total, francs 33. (Always a *timbre*; you can't even file a protest with the Préfect without addressing him on stamped paper.) Thus one sees the procedure is not cheap, and you ultimately have to pay that tax on your essence as well, so that it does not pay to run by.

The *procès-verbal* of the octroi or a *contravention à vol* are accidents of the road which one must be prepared to meet with

## The Gates of Paris

in France, unless they happen to be forewarned and forearmed. The *contravention à vol* is most difficult to protect yourself against. It is sudden, subtle, and usually premeditated. It depends upon the humor of the *gendarme*, or the agent, who hauls you up, as to whether he has had a good dinner, or a bad one as like as not. It is as much this as a desire on his part to make you respect foolish laws which are nothing to him personally, but which give him endless opportunities.

One word of advice: if a *procès* is instituted against you accept with as good a grace as possible, for the *gendarme* of France is but human. If you exasperate him—and the chances are that you will if you don't hold yourself in—he will push you to the last limit, and instead of a modest fine to be paid over the counter of the nearest *gendarmerie*—a ready-money, quick transaction—or a dismissal of the entire charge by the brigadier in charge (he perhaps having dined well) you will probably be held up three or five days in a dull little country town eating your head off in a country inn and playing *piquet*, *boston* or *dame*—perhaps with the brigadier himself. It's nothing much of a horrible fate, but it is not for a moment to be compared with the joys of the road.

Agitation is ever rife in France as to the suppression and modification of the octroi on the food for automobiles. One proposition was actually put forward recently to suppress the tax on essence and put a *taxe de séjour* on automobiles of one franc per day for all the time they remained within the fortifications of Paris. Thus did the *ville lumière* seek to equilibrate its budget. Surely the cure were worse than the complaint, from the automobilist's point of view. A million and a half francs was to be raised in this way, and with less labor involved in collecting it. But what about that army of octroi employees who would be left without occupations?

The actual sum totals received from travelers entering the gates of Paris, by road, railway, and tram, rise to an incomprehensible figure. Nearly six hundred million came to town by rail alone last year, and each and every one was liable for a tax on a bottle of wine which he might be bringing to a sick friend, a fowl, or a rabbit, or a half a dozen "new-laid," which the Frenchman calls *a la coque*.

Paris, the most brilliant and glorious of the world's capitals, with its million and a half of industrious and prosperous souls, has to eke out its revenues by taking the essence of the automobilist who already is a larger spender of money than any other class who enters the iron grilles of the great gates. Yes, Paris collects of the automobilist down to the last centime, though she does it by rule of thumb, the last fifty centimes of tax not leaving enough essence free to allow you to reach your wife's dressmaker's or the chic restaurant where you proposed giving a golden banquet

to some visiting compatriot, and thus keep money in circulation. Really it is a *peu banal*; there is no question about that, and it only proves that Paris, with all its splendor and attractions, is full of contradictions—it welcomes you with one hand and waves you away with the other.

Anyway, save the gates of the Bois and some of the minor exits and entrances, the octroi gates of Paris are open to pass the belated traveler throughout the night, and are not closed tight like the *grilles de la morte* of Versailles and Macon. Look out for these if you are passing that way and are out late at night.

There are some localities in France which have so modified their octroi regulations that they hang more heavily on automobiles than they do on hippomobiles. The automobile pays a very heavy tax to begin with, whilst the horse pays merely a nominal one, and their food of gasoline and oil pays the octroi, where horse-fodder comes in free. Here's the case at Lyons: An automobile of 20-horsepower (which the French call *chevaux-vapeur*) which already pays a state tax based on the number of inhabitants in the commune in which it is registered, also pays a *taxe indirecte*, the *impôt* on essence. From this, one figures that the flesh and bone horse does not pay more than 10 per cent. of the tax for his right to live and work that does his descendant in bronze and steel.

For actual collar-work the *cheval à quatre pattes* develops (in starting) a force, perhaps, equal to twelve mechanical horsepower, and it is for this reason that the three-horse Parisian omnibus of the Nineteenth Century is being replaced by the Twentieth Century autobus of from 25 to 40 horsepower, to do the same work. The *cheval à quatre pattes* pays a yearly tax of 5 francs 60 centimes, and the autobus in Paris pays 90 francs and 5 francs a horsepower for its forty mechanical horses—in all 290 francs, and some odd francs besides, and always that tax on gasoline and oil, and that's no small thing, as has been shown.

One-third of the population of France lives beyond the pale of the octroi. By means of this tax is raised the enormous sum of considerably over three hundred million francs. How much of this is actually paid by the automobilist is not shown in the returns, but the proposition must be figured large, as large as that paid by any one other single class. The octroi tax in France, with very little modification, is a legacy handed down from the Romans when they were running things up and down the breadth of Gaul. They knew not automobiles and they knew not automobilists, but before the present generation of tax gatherers have entirely died off the automobilist will probably be heard from—in this respect as he has been with regard to good roads. Not that he has been entirely supine in the matter up to the present moment, but action has not yet assumed definite form.

**IN THE BOIS.**—Maximum speed allowed: twelve kilometers an hour.

On *routes non carrossable*, bridle and cycle-paths automobiles may not enter. Automobiles are absolutely prohibited in the Pré Catalan—the nurse-maids' and children's playground, and the Allée des Acacias—that *cadre d'elegance*—between noon and 7 P.M. This is because the *grande monde*, or enough of it possessed of influence, object to the odor of petrol as being an exotic perfume to which their sense of smell, used only to those odors of the stable and the garbage-heap, are not yet accustomed. Whyever do people object to the unburned fumes of petrol; it's a good clean smell, a purifier probably, and perhaps healthful. With burning, dripping oil the case is different, but none of the present-day automobile breed offend in this manner. If one drives an electric in the Bois, the Allée des Acacias is open to him. So much for an inducement for the modern manufacturer to make a silent petrol motor—if he can do it without throttling all its force, which is doubtful. What about the steam car!

The gates of the Bois are closed at midnight, but the Administrateur des Services d'Architecture et des Promenades et Plantations, to give him his full title, which doubtless he would want one to do, will give you a Carte de Circulation, valuable for a year (at a cost of thirty francs) before which the minions who guard the gates in the small hours of the night will bow respectfully—and still more respectfully for passing of a fifty centime *pourboire*. The only possible reason for one's wanting to enter the Bois after the gates are closed at midnight is to get a smooth, clear road in and out of town, crossing the river at Suresnes.

Here's another thing to look out for:

Article 8 of the law of locomotion now in vigor in Paris, though it was promulgated in Revolutionary times and bears the date of 2 Brumaire de l'An IX., prescribes that no *voiture*, whether propelled by a horse or other means of locomotion (was this prophecy?) shall cut through a funeral cortège, a file of soldiery, or a party of young misses going home from school. The boarding school *queue* was, apparently even then an institution that was duly respected and officially protected.

**NUMBER PLATES IN FRANCE.**—Every automobile circulating on the roads of France must be passed, as to its proper mechanical construction, by an inspector of the Département des Mines, by personal inspection by an employee thereof, or by having the *passavant descriptif* supplied by the manufacturer endorsed. This *passavant descriptif* is simply a categorical description of the marque and model and its constructive details given by the manufacturer, and corresponding in every particular with another of the type previously passed upon by the government inspector as being a fit and proper and well-behaved automobile. It is from the lack of the *passavant* that all foreign automobiles are obliged to pass before the critical, inquisitive eye of a rubicund little Frenchman, usually fat and round and with a red ribbon in his button hole. It is he, too, who puts you through your paces as to your ability to start and steer the thing as well, which, fortunately, for many, is the Alpha and Omega of the automobile curriculum as

it is known to the representatives of officialdom in France. Automobiles in France capable of running at a speed greater than thirty kilometers an hour must bear a number-plate—white letters and figures on a black ground—with the dimensions of those at the rear 25 per cent. greater than those at the front; this on the supposition that the eagle eye of a gendarme may thus more quickly not the number of a flying auto and make literally a *contravention à vol*, which is nothing more nor less than springing an accusation upon you, not at the time the offense was committed, but at some future time when it little suits you, and perhaps prevents you from stating your case at all.

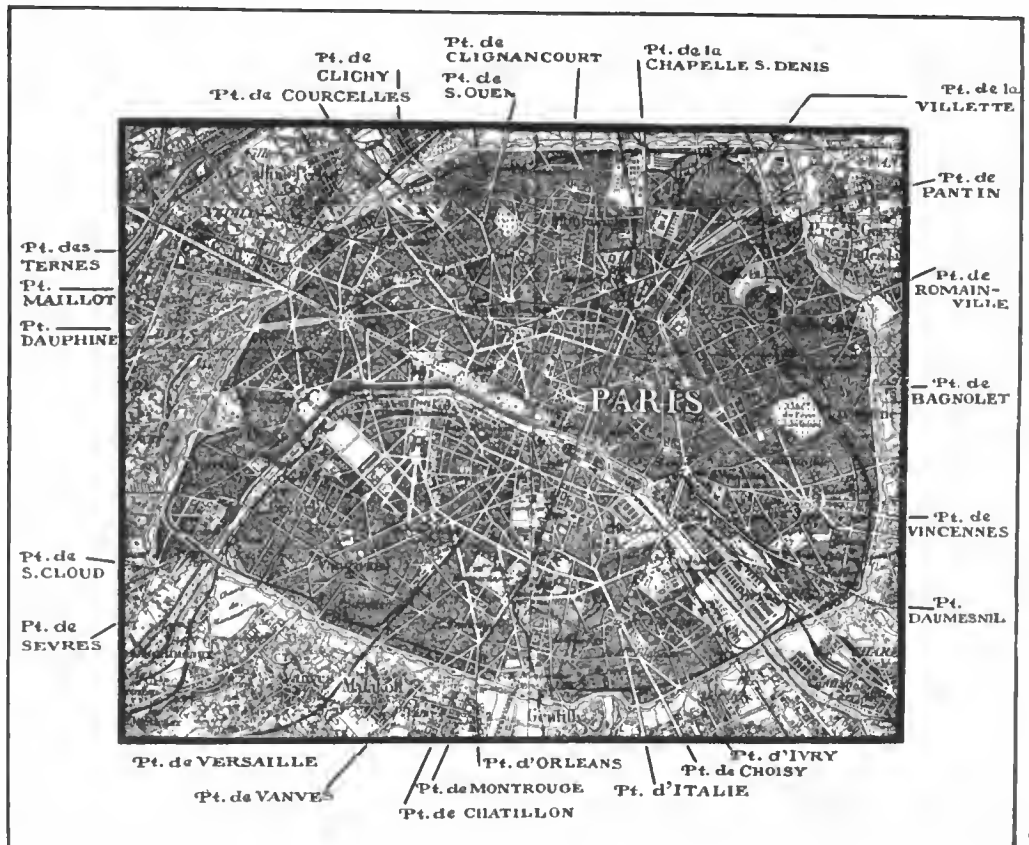

Automobile number-plates in France bear the letters of the Arrondissements Mineralogiques under which they have been issued. A number-plate issued by one arrondissement is good throughout France, and also in Algeria and Corsica, without any other formalities.

The largest number of automobiles are, as might be supposed, registered as from Paris—Seine—4,627, and the fewest from the Département of Lot—32, Haute Savoie—31, Hautes-Alpes—20, Basses-Pyrénées—13, Lozere—9, and Ariège—21.

**THE AUTO TAX IN FRANCE.**—According to the "Loi du 10 Juillet, 1900," *voitures automobiles* are taxed in France according to the following table.

You pay less for a low-powered car than you do for a high-powered one, and you pay less for a two-seated car than for a four-seated one, and again you pay less all around if you live in a small town instead of a big city. Take it all in all, it seems a fair way of taxing automobiles, and the best proof of this is that the automobilist is not kicking on the imposition of the mere tax on the machine, be it great or small. Taxes are spent, or supposed to be spent, for the benefit of the tax-payer—what is not absorbed by officialdom—and so long as the tax on automobiles is not outrageous, and so long as the automobilist gets good roads for his money, the tax is quite worth the paying without grumbling.

This was the old turnpike idea—and it was not such a bad idea either; now let some benefactor, or mere speculator if you like, build exclusive automobile roads and charge for running over

THE GASOLINE DEALERS OUTSIDE THE GATES OF PARIS.

them and watch him get business and perhaps become wealthy. The following is the scale on which you pay your automobile tax in France:

Cities or Communes	One or two seats	Two or more seats	For each H.P.
Paris .....	50 fr.	90 fr.	5 fr.
Communes of more than 40,000 habitants .....	40 fr.	75 fr.	5 fr.
20,001 to 40,000 habitants.....	30 fr.	60 fr.	5 fr.
10,001 to 20,000 habitants.....	25 fr.	50 fr.	5 fr.
10,000 hab. or less.....	20 fr.	40 fr.	5 fr.
Motorcycles with one seat (including tricycles).....			12 fr.
Motorcycles with two seats (including quadricycles and tri-cars) .....			24 fr.

If you don't pay your tax on demand, after having first declared your automobile at the *mairie*, the tax is doubled. Result: quick returns for the tax collector.

**WHEN IS A CARRIAGE NOT A CARRIAGE?**— Madame X—, who lives in one of those typical and splendid Paris apartments with a courtyard, in the Etoile quarter, has recently sued the owners of the building for not allowing her to drive her last new delight in the automobile line inside the hallowed portals. Previously she had maneuvered, or her smuggy-puggy coachman had for her, her pair of dock-tailed equines attached to her coupé, landau or brougham. The beasts stamped and neighed and committed other indecencies to which no one objected, but her last new joy, a *dernière modèle* of an automobile, was an outrageous and unholy thing, even though it really made no disturbance. The neighbors complained; they didn't possess an automobile themselves, it may be supposed. Anyway, the automobile of Madame X— had to stand in the gutter by the curb, and that good lady, instead of being able to step from her carriage into her house under cover had to make her dusty or muddy way across twenty feet of pavement.

This was because the *concierge* was deaf to the call of "*cordon s'il vous plaît*" whenever Madame came and went. He was an autocrat first, like all Paris *concierges*, and an autophobe after. "*Ces sales choses là*" should not come within the frontiers of the little land over which he ruled as dictator.

Madame X— promptly took the case to the courts; she paid 16,000 francs a year *loyer* and she didn't see why her automobile should not be treated with the same consideration as the horses of her neighbors. It was house-broke.

The procès dragged as law cases will, and meantime Madame's automobile was allowed to get no nearer her door than the curb. It seemed likely that aeroplanes would come into common use before the status of Madame's automobile was legally decided, and then a claim would have to be put forward demanding that the latch string of the skylight should be left out all night. This would be a new complication to set the judiciary all agog. The Paris bench and bar had never had such a case before

and so they debated with all that explicitness of which the French language is capable, and the parties to the action, one and all, got more and more indignant.

Finally, *Voilà!*—the owner could do as he liked about compelling his *concierge* to open the great door promptly at any hour of the day or night to Madame's automobile, but each time the lady was kept waiting fifty francs would be knocked off of her rent. At this rate, if the thing happened only once a day, Madame might have her apartment rent free, and accordingly she was content, for she had a "three, six or nine" years' lease, and she had hitherto paid her rent promptly. Another automobile victory, and they are still coming down the line.

**AU PAS.**—Once and again, even in enlightened France, one sees in some broad city thoroughfare, in Paris even, a staring blue and white warning with the words "*AU PAS*" boldly lettered thereon. True, there are many official admonitions which are worthy and ought to be respected, but to increase and multiply them needlessly is to admit that the automobile is a wild, uncontrollable thing as compared with the two-wheeled butcher's, baker's and grocer's cart, usually driven by a lad of sixteen, at a speed around corners of anything he likes, dangerous to himself and all the world.

Automobiles, supposedly rushing at a death-dealing pace, have before now been measured and timed in London and Paris with astonishing results in their favor. Their speed has usually worked out at something like twelve or fourteen miles an hour, the cabby and his charge at eighteen, and the butcher's boy at twenty or more. Which is the more dangerous? Which is the more radically controlled—the horse with a pair of leather thongs and a bit in his mouth for a brake, or a modern automobile which can pull itself up when going at forty miles an hour in a quarter as many feet?

"*Au Pas*" was probably meant for someone besides the automobilist originally, but the municipal guardians of that vague entity known as the public who are usually against everybody, say: "*Vous avez marcher contrairement aux réglemens*"—at a greater speed than is allowed.

*Au Pas!* What is "*au pas*"? The speed at which a veteran of the Crimea ambles along as he takes his walks abroad, that of a postman, the average mortal, say three or three and a half miles an hour, that of a horse, a child, or what? It is the habitual rate of progression at which an able-bodied man walks, so say the courts, though evidence has been forthcoming to prove that the sign was originally put up to bring the horse trot, canter or gallop down to a walk.

"*Au Pas*" then; the walk of a man, but, as the French automobilist cries out, "*Quel homme!*" A young man, an old man, a sandwich-man, or a *chasseur à pied*? There's a difference.

In all probability these signs are soon to be buried, along with that other curse of the French automobilist, the Louis Quatorze *pavé* which, in the gallant days of old, was so generously besprinkled all over France, and which still remains in detached strips here and there as effectual a means of bringing one's speed down to "*au pas*" as any other extant.

# Next the Garden Innings of the Importers

A GROUP of eighteen firms as representative of the European automobile industry cannot be taken numerically as an indication of the size of the movement on the other side of the Atlantic. Yet the cars to be shown to the American public when the doors at Madison Square Garden are flung open next Saturday night will not fail to be interesting from the fact that they are, on the principle of the survival of the fittest, the best that the Old World can produce in the shape of an auto. Competition with vigorous America has not been run on the lines of sentimentality, but of mechanical superiority and business acuteness. The eighteen, therefore, that have survived the industrial struggle are worthy of close attention if for no other reason than that they make a bold stand for popularity in face of international competition.

With such firms as Renault, Delaunay-Belleville, and Panhard-Levassor representing France; Maja for Germany; Fiat for Italy; Martini for Switzerland, and Rolls-Royce for Great Britain—to mention only a few—the lover of imported cars will have enough to interest him, and the student of automobiles will find in the best of four countries plenty of material for observation and comparison. It is declared that in every case 1908 models will be on view, and there is no reason why they should not be, for there has been a sufficient interval between the closing of the grandiose Paris display and the opening of the more modest event in Madison Square to admit of their transportation. No one with any conception of the scale on which European shows are held will expect to see the press agent's story of a Paris Salon Transplanted carried out to the letter, and consequently will not be disappointed. But so much has been said on the

artistic dress of a hall which is not the best in the world for decorative effect that the promoters will have to accomplish much to eclipse the best efforts of American promoters.

In the accessories section natives and foreigners are about equally divided. A few of those holding stands on the mezzanine floor put forth their products for the first time this season, but the majority have already exhibited at one or both of the exhibits in this city. Consequently, except for those who really mean business, there will be less of interest here than on the main floor, where cars are exhibited.

Coming at a festive season of the year, it is appropriate that a tone of seasonable gaiety should be rung into the big hall. This is promised in the form of an artistic setting with plenty of room for the lounge, where the *flanerie* of the grand boulevards will be encouraged and even made delightful. Chief among the social functions is a banquet on New Year's eve which will gather in the *élite* of the importers' world and not turn away those interested in their products. The following is a complete list of the cars and firms represented:

**RENAULT**—Renault Freres Selling Branch.  
**RENAULT**—L. P. MacNamara.  
**DELAUNAY-BELLEVILLE**—Palais de l'Automobile.  
**MAJA**—Maja Company, Limited.  
**PANHARD-LEVASSOR**—Panhard & Levassor American Branch.  
**BAYARD CLEMENT**—S. B. Bowman Auto Company.  
**BIANCHI**—Percy Owen.  
**C. G. V.**—C. G. V. Import Company.  
**DARRACQ**—Darracq Motor Car Company.  
**DELAHAYE and PILAIN**—Delahaye-Pilain Import Company.  
**DIETRICH**—Dietrich Import Company.  
**FIAT**—Fiat Automobile Company.  
**HOTCHKISS**—Archer & Company.  
**ITALA**—Itala Import Company.  
**ISOTTA-FRASCHINI**—Isotta Import Company.  
**MARTINI**—Martini Import Company.  
**ROCHET-SCHNEIDER**—Auto Import Company.  
**ROLLS-ROYCE**—Rolls-Royce Import Company.

**Renault.**—Prominent among the cars shown by the Renault Frères will be the new six-cylinder chassis with cylinders of 4.7 by 5.5 bore and stroke cast in pairs, given a catalogue rating of 50 horsepower. This model, as well as the larger four-cylinder cars, will be fitted with an automatic self-starter, designed by Louis Renault and exhibited for the first time in America. A small, air-cooled pump on the forward end of the chassis and driven off the camshaft compresses air into a tank attached within the frame. Communication is made from the compressed air tank to an operating lever on the dashboard, and from here to the cylinders by suitable piping. By pulling down the lever air is admitted from the tank to a distributing valve above the cylinders, through which it is carried into the cylinders in correct sequence at what would ordinarily be the firing point.

No radical changes have been made in 1908 Renault models, but a great deal of attention has been given to the refining of details and to rendering still more accessible a car which has always been admitted to be one of the most conspicuous in this respect. There is further a uniformity of design in all models from the smallest two-cylinder to the largest six-cylinder car, which of itself is proof that Renault has long passed the experimental stage. Among the refinements are some changes on the car to facilitate the dismantling of the radiator. There being no pump and no fan, except in the flywheel, the cooling system is

a model of simplicity. To dismantle the radiator on the new cars all that is necessary is to disconnect the inlet and outlet piping and withdraw a bolt on each side of the frame, when the radiator can be lifted out of the channel in which it rests against the dashboard, the operation requiring but a few minutes.

Five models of four-cylinder cars are built, varying in size from a 35-45-horsepower touring car or limousine to a 10-14-horsepower town vehicle. At the end of the list is a two-cylinder, 8-horsepower car used very extensively in various European capitals as a taxicab. Instead of the compressed air self-starter, the smaller models can be fitted with an entirely mechanical contrivance for starting the engine from the driver's seat merely by pressing down a foot pedal.

**Delaunay - Belleville.** — The old-established firm of boiler makers, established at Saint-Denis for over one hundred

years, has paid special attention in its automobile factory to the production of six-cylinder cars. There are two distinct models of sixes, one rated at 40 horsepower and having its cylinders cast separately, the other having its six cylinders cast in two groups of three and catalogued at 15 horsepower. There are four other models, each with four cylinders, rated at 15, 20, 28 and 40 horsepower. The three smaller models have shaft drive; the three powerful cars are fitted with final drive by side chains.

Certainly the most interesting vehicle in the series is the new 15-horsepower six-cylinder chassis town vehicle, for which service it has been specially designed and which may be classed as one of the finest products of France.

The six-cylinders are 3.3 by 4.7 bore and stroke, forming two groups of three each, with valves all on one side, giving a compact, clean-cut and fully accessible motor.

**Maja.**—The one name at the Importers' Salon which will be strange to the ears of Americans is curiously enough connected with the oldest and best known house in the automobile world. Maja is the younger sister of Mercedes, produced at the Austrian factory of the Daimler Motoren Gesellschaft. Two models are promised for the American show, one being rated at 28-35 horsepower, the other at 35-40 horsepower. In general features the Maja is a reproduction of the Mercedes, but unlike her better known relative can be obtained with either shaft or chain drive.

Among the more important features in which the Maja differs from the other automobiles of the premier German factory may be mentioned the method of operating the ignitors of the low-tension magneto ignition. Instead of being placed on the side of the combustion chamber and being operated by vertical tappet rods, they are now contained within a specially formed inlet cover. They are connected by horizontal tapped rods, all commanded by a double cam which is carried to the top of a vertical shaft situated between the two pairs of cylinders. This shaft is driven by worm gearing off the inlet valve camshaft and its position can be varied sufficiently by a sliding rotary movement to advance or retard the point of ignition to the usual requirements. In order that the firing of each cylinder may be verified without opening the bonnet, as is usually necessary, there are four plugs placed outside the dashboard in such a position that the driver can immediately and separately test each cylinder with the minimum of trouble.

**Panhard-Levassor.**—A four-cylinder 15-horsepower live axle Panhard chassis will form the center of attraction at the stand of this leading French firm. It is the first time in the history of the house that a touring car with other than chain drive has borne the name of Panhard, though shaft-driven racers were built a few years ago. Instead of the armored wood frame which has always been associated with Panhard, it is now of the ordinary pressed steel type, channel section. On the 15-horsepower model it is not narrowed in front, this, according to the makers, being a source of weakness, but the rear ends are set upward. Suspension is by semi-elliptic springs in front and three-quarter elliptics in the rear, these latter being attached to brackets bolted to the frame. The four vertical cylinders of the engine are cast separately, with valves on opposite sides, bore and stroke of the cylinders being 3.5 by 5.1 inches. One of the most interesting features of the new Panhard models is the sliding camshaft actuated by a pedal, and operating the exhaust valves, by means of which the engine can be used as a powerful brake with no extra weight to the car and the addition of very little in the way of mechanical extras. Both camshafts are enclosed in the upper portion of the crankcase and can be withdrawn from the rear end by removing a detachable disk. Each valve tappet guide is formed with its flange so that it is a comparatively easy matter to dismount any of them.

**Clement-Bayard,** or Bayard as it is called in the land of its origin, to distinguish it from a rival firm with the same name, will be represented mostly by cars of high power, though the Levallois factory is this year producing a large series of models from the small taxicab to the most powerful touring car.

**Bianchi.**—Some of the finest of Italy's high-grade cars will be exhibited on the Bianchi stand backed by Percy Owen, Incorporated. The firm, although only starting in the automobile business towards the end of 1905, has now three factories, one at Brescia and two at Milan, where, in addition to pleasure cars, a good deal of attention is now being paid to commercial vehicles. The Milan factory, equipped with \$400,000 worth of American machine tools, is considered one of the finest in Italy.

**C. G. V.**—A handsome town chassis with shaft drive and steering wheel on the left instead of the right-hand side will form the principal attraction from the Charron factory for 1908. This is in reality the continuance of a model placed on the market a year ago with considerable success. It has shaft drive and an interesting type of rear suspension by C springs.

**Darracq.**—Although all previous models from the Suresnes factory, from single to six-cylinder cars, will be continued, the outstanding feature for 1908 will be the four-cylinder car, designed first for taxicab work and now used for touring and similar general service. These have already been introduced to New Yorkers by their service as taxicabs, but no opportunity has been given heretofore to examine them in detail.

**Delahaye and Pilain.**—The one from Paris, the other from Lyons, both these French makes have a good reputation in their own country. The Delahaye is produced in a number of sizes from small two-cylinder taxicabs to powerful six-cylinder cars, while Pilain is almost entirely confined to cars of moderate horsepower, though sufficiently powerful for touring.

**Dietrich.**—Because it is the latest arrival to the Dietrich family, the shaft-driven car of this firm will be examined with more interest than the better known chain-drive cars from Lunenburg. The new model has a special double drop frame, designed to give a very low side entrance.

**Fiat.**—Seven distinct models will be produced from the Fiat factories during the next season, the series comprising three shaft-driven cars and four with chain drive, among the latter being two six-cylinder models.

**Hotchkiss.**—A handy four-cylinder town vehicle, and a powerful six-cylinder model will vie with one another for first attentions at the stand of the French gunmakers. In the town car the four cylinders have been cast in one block, ignition is by high-tension Eisemann magneto, and, naturally, final drive is by means of propeller shaft.

**Itala.**—Though not entirely a newcomer to the automobile world, Itala was only brought prominently before the world a couple of years ago by a series of successes in international speed contests in Italy and France. The models are based largely on the Mercedes type and have a reputation in Europe for correct design and excellent workmanship.

**Isotta-Fraschini.**—Another Italian firm which has sprung up since 1905 and already earned a reputation in the construction of the automobile de luxe. Recently the firm has passed under the control of Dietrich, but the models shown for 1908 are all the work of Italian engineers.

**Martini.**—Switzerland's rifle firm is also one of the pioneers in the automobile industry, having a history which dates back more than eleven years. Being built in a land of mountains, the product of the firm has always been noted for its hill-climbing powers, some of the Martini's greatest honors being won in open competition in the mountains.

**Rochet-Schneider.**—Another foreigner created in a land of mountains and bearing all the characteristics of a machine built where impossible grades are the commonalties of life. The Rochet-Schneider car was first put on the market in 1900; in 1904 the concern was made an English limited liability company, and its head offices removed to London.

**Rolls-Royce.**—Six-cylinder automobiles are devoting the entire attention of the only British firm holding space at the Importers' Salon. Rolls-Royce has won some fame in America by capturing a special gold medal for a 12-mile race at Ormond against an American car.

date  
could

PARIS, Dec. 14. —  
for the French  
night of July on a course  
numbers 1, 2 and 3 are from the  
sur-Sambre, and will be driven by Degrais, Perpere and  
Brault, who handled the three Germain stripped touring cars in  
last year's Grand Prix.

Two days ago the Sporting Commission of the Automobile Club of France met in full force and gave official confirmation of its adoption of the international racing rule adopted at Ostend by every recognized automobile club except America, under which bore for four-cylinder engines must not exceed 155 millimeters (6.102 inches) and weight must not be less than 2,425 pounds, empty. Next morning Secretary Sautin received a check for \$2,400 and the official engagement of the three Germain. It had been decided at the meeting to reduce the entry fee in every case where more than a single car was engaged. One thousand dollars is the fee which must be paid to put one car in the race, but for teams of two the fee is \$1,800 and for full teams of three \$2,400. As single entries are rare, the reduction is a clear saving for automobile constructors.

This is the first occasion on which less than \$1,000 per car has been fixed as entrance fee for an international automobile race, and has been made possible by the more economical administration of Victor Breyer, manager of last year's event on the Dieppe circuit. Under the same excellent administration a substantial credit balance is certain next year, for the race will be

of the change  
intending to take part  
months before the test, well advanced  
a few cases, indeed, where racers are already  
certain that the winner will not be found in the  
leaves the factory.

Last year's circuit near Dieppe is still favorite for the race, but will be close pressed by half a dozen others. At a recent meeting between the Dieppe authorities and the club it was officially announced that the township would guarantee to raise a subsidy of \$10,000 and might even double this if necessary to induce the club to hold the race in its district. There is an opinion among certain members of the Racing Board that some other district should be chosen this year, in order to develop automobile enthusiasm in different parts of France, more especially as there is a strong league at work against automobilism.

Six other circuits have been selected for consideration, comprising the districts of Morvan, Loiret, Cher, Marne, Rhone and Bretagne. All can offer an excellent course of 40 to 60 miles in length, in every way suitable for a 500-mile contest, but the selection will depend on local support and it is in this feature that Dieppe is particularly strong.

**AN EPOCH IN THE AUTO TRUCK BUSINESS—FOURTEEN CARS TO ONE CUSTOMER BY THE LOGAN CONSTRUCTION COMPANY.**

This shipment was made Thursday, December 12, by the Logan Construction Company, from its factory at Chillicothe, O., to the St. Louis *Post-Dispatch*, and is claimed to be the largest shipment ever made to a single customer for this type of car. The cars will be required to make four trips daily delivering newspapers, the trips varying in length from four to fifteen miles. They will replace three times their number of horse-drawn vehicles.

# THE FUEL SYSTEM OF AUTOMOBILES

By THOS. J. FAY, E.E.

A COMBINATION of hydro-carbon vapor and atmospheric air serves as the fuel in automobile motors at the present time, and it is probable this fuel will continue to be the main stay, for some years, at any rate. In view of this fact, it seems as if the several questions of its production and use should be well understood, not only by the makers of automobiles, but by the users of them as well. Whilst it is true that much has been said about this fuel, and many autoists are well informed, even so, it will stand some further discussion, it is believed. Beside the hydro-carbon products, as gasoline, there are other sources of supply, amongst which alcoholic vapor with atmospheric air and synthetic mixtures, having for their base alcohol on the one hand, and gasoline in some cases.

The fuel question from the autoist's point of view involves more than the mere matter of the genera of the fuel, and it will be a step in the right direction to discuss the details interesting to the user. There are few who do not know how illuminating gas is produced, and of those who understand its production very well indeed, many would be surprised were they told that "a little gas plant" exists on every automobile. True, the gas is used as produced, and the familiar "gas holder" is missing. It would be quite possible to take the automobile gas plant, quite as it is, and adapt it to the purpose of providing illumination in the home. It would not be cheap gas to use for such purposes, but that is not important, since the cheaper gas is to be had on every hand. Equally true, illuminating gas, as used for lighting, works perfectly well in motors, and would do for automobile work. It would even serve better, and it would be cheaper to use; but a gas holder (gasometer) on an automobile would weigh over much, and the space it would take might ill be afforded. At all events, in the automobile, the gas plant is very simple, and it might even be called primitive.

There are advocates of the plan involving the use of stored gas for automobile work, and it cannot be safely claimed that the scheme is without its due measure of merit. On the other hand, liquid fuel is in a more condensed form, and is in a more stable state of equilibrium; hence liquid fuel is very convenient, although a still further state of condensation would be by way of "solid" fuel, with a melting point below the temperatures, normal to the surrounding. This question is not unheard of, since alcohol will lend itself to the purpose, but the time is not ripe to thrust the solid fuel problem to the fore.

## Concerning the Fuel Tank.

The liquid fuel holder for gasoline may be a tank of copper, capable of holding gasoline under a pressure of about two pounds per square inch; the capacity of the tank to be about twenty times the piston displacement of the sum of the cylinders. This is to say, a four-cylinder motor with cylinders, 4 inches bore and 4 inches stroke, would have a total displacement of 201 cubic inches and 20 times this would be about 4,020 cubic inches of the fuel tank. In other words, or approximately, 17 gallons. In this way it is possible to decide upon the approximate desirable capacity of the fuel tank for any sized motor. Steel tanks are not so good for the purpose, since water is likely to settle in the bottom of the tanks and the rusting process that is likely to follow will, in time at any rate, become a great source of annoyance. Cornice copper serves very well the purpose, and the ease with which it fashions into shape is one of its strong points. It is not unusual to use 16-ounce copper for the girth, and 20-ounce copper for the heads, measuring in ounces per square foot. If the tanks are to be large and long, they require to be partitioned off to prevent the liquid from piling up when the car negotiates curves at a considerable speed. The partitions should be perforated to enable the fuel

to reach its level quickly, and the same partitions are of further value, as they serve to strengthen the tanks considerably.

There is one other point about the capacity of tanks, to mention which will be in order. The amount of gasoline required for the various motors depends upon the number of cylinders, rather than upon the total piston displacement. The difference may be approximated about as follows:

- (a) Single-cylinder motors, allow 26 miles to the gallon.
- (b) Double-cylinder motors, allow 19 miles to the gallon.
- (c) Quadruple-cylinder motors, allow 13 miles to the gallon.
- (d) Sextuple-cylinder motors, allow 10 miles to the gallon.
- (e) Octuple-cylinder motors, allow 7 miles to the gallon.

These allowances must be but rough approximations, because there are a variety of considerations beside the question of the

FIG. 1.—Sectional view of standardized carburetor referred to in the accompanying article.

number of the cylinders. Some motors will perform in a superior way, and thereby serve as exceptions to the approximations; and again, the weight and design of the car in each case will introduce a variable. The matter of the six-cylinder motor, now so much in vogue, and the expediency of the use of so many cylinders, becomes a much mooted question, from the point of view of the fuel, and the values above set down are bound to cause some uneasiness on the part of the builders of such motors. It is not the intention here to go into this matter any more than to point out the fuel requirement, but to leave this part of the subject without giving at least one reason why the fuel requirement increases with the number of cylinders would be unwise.

In a motor of eight cylinders there are eight times as many piston rings as those of a single-cylinder motor, and, if each ring dissipates in heat, as a result of friction, say, 0.25 horsepower, then it is plain to be seen that 103,800 B. T. U. of heat are lost in the process as against 12,725 B. T. U. of heat in the single-cylinder motor. This is on the assumption that some 12,725 B. T. U. of heat must be supplied in the fuel for each one mechanical horsepower developed. Of course there are good reasons for using multiple-cylinder motors, but economy of fuel is not on the list. It follows, then, that the size of the fuel tank must be influenced by the number of cylin-

ders in the makeup of the motor in any given case; moreover, high speed has its "windage" to be taken into account. The fuel tank should also allow for the nature of the roads over which a car must be driven, since the fuel requirement will be a variable, depending upon the nature of the roads.

Nor does it follow that the most fuel will be used on the very inferior road, since a car at a high rate of speed might burn up more gasoline on a good road than would be used by a car at a low rate of speed on a road not so good. Indeed, the whole matter is one hedged in by the several conditions, and it is only possible to fix the results if the conditions are also definitely established. It was said, one horsepower represents, in round numbers, some 12,725 B. T. U. of heat. Certainly, this amount of heat has a mechanical equivalent, greater than one horsepower, but the thermal efficiency of the best of the internal combustion motors is far from 100 per cent.

In the English system of notation, it will be remembered, heat is measured in such terms as to render one British Thermal Unit (B. T. U.) as equal to 778 foot pounds, according to Prof. Rowland, although the original "Joules" equivalent was set down as 772 foot pounds. At all events, the B. T. U. is more definitely described as: *That quantity of heat which will raise the temperature of one pound of pure water 1° F., considering the point of maximum density of water, which is said to be 39.1° F., nearly.* In this, we have a means of making comparisons, and with this means it is possible to set down the data at hand and approximate some conclusions. In the first instance, the thermal efficiency of a good gasoline motor may be so high as 20 per cent., hence it is plain that the value of the gasoline in thermal units must be at least five times more than the mechanical power.

One horsepower hour represents 2,545 B. T. U. per hour, and  $2,545 \times 5 = 12,725$  B. T. U. required in the fuel per horsepower, mechanically developed. Plainly, then, increasing the mechanical requirement in any way increases the fuel requirement some five times the mechanical increase. Moreover, this is a low value to be realized, under the best conditions only; provided the motor is allowed to operate at the most efficient point on its characteristic curve. These matters are, on occasions, befogged, because in the scramble for other advantages the absolute facts are disregarded. True, little attention is paid to the question of thermal efficiency, and the amount of gasoline required is left to be settled for by the owner of the car. This in itself is not a matter over which to lament, since it is the purchasers of cars that must decide if they want high thermal efficiency or high speed.

#### Some Details of the Gas Plant.

The liquid fuel reaches the carbureter through copper piping, impelled by either pressure on the fuel tank, or if the tank is elevated, through force of gravity. It is not uncommon to find the piping a little too small in diameter, too flimsy to possess the requisite endurance, and most likely to become obstructed by jelly formations, or from other causes. Most of us know that the building laws require a 4-inch pipe as a minimum size for sewer connections, not because a smaller pipe would be too small to conduct away the sewage, but for the reason that the 4-inch size will not dam up of its own volition. The same holds for gasoline pipes, in the same way, but, fortunately, a 4-inch pipe is not necessary to prevent the dam. A 3-8-inch pipe serves very well indeed, and it is also mechanically strong enough to possess the requisite endurance. This piping will be a little heavy, to be sure; but it would be better to use less castings elsewhere and have the gasoline piping in more stable shape.

Piping is sometimes so installed as not to be accessible; this is really much to be avoided, since it is just such installations that are likely to give trouble, as piping so placed will have a hole chafed in it, and in cramped quarters no one can be sure the piping does not rub against edges of laterals, of the chassis

frame, or some other abrading surface. There should be no joints in the piping between the tank connection and the carbureter connection, primarily because such joints serve no useful purpose, and again, they are not necessary. The best of joints are more or less prone to give trouble, and as they are oftentimes made they are sure to go wrong.

The carbureter may be one of several types, structurally, but in principle, the differences are not so great as one might suppose, judging from looks alone. At all events, the carbureter is but a miniature gas plant, the function of which is to impregnate atmospheric air with liquid (gasoline) in the right proportions, and in such finely divided form as to render the mixture highly inflammable. The explosive feature may be best understood if it is merely considered as the product of restrained energy, and the energy is set free in the process of burning the mixture. If the mixture is highly inflammable, it is plain to be seen the energy will be set free in the shortest space of time, and will then develop the maximum of the explosive phenomenon.

The carbureter, then, can widely control the results, since, if the mixture is rendered slow-burning, the time taken to propagate the flame will be long, and the effectiveness of the explosive effort will be diminished. On the other hand, the amount of energy in the mixture can be varied, by altering the ratio of gasoline to air, and the real problem is to produce a mixture, holding the maximum amount of gasoline, without diminishing the rate of propagation of the flame, to a point likely to dampen the ardor of the effort. The mixture is not, properly speaking, an explosive, since it does not give up the energy fast enough to disrupt the enclosing members; the rapid expansion of the inflamed gases does certain work, but the rate of expansion is not so rapid that the piston cannot get out of the way ere the pressure reaches a magnitude exceeding the controllable value.

The carbureter, then, is intended to produce a combustible of acceptable characteristic; a combustible in fact rather than an explosive, by rendering the mixture "slow burning" rather than gunpowder, but quick and complete combustion relative to coal. The internal combustion motor is one in which the fuel is used directly, and the carbureter takes the place of the coal bin, while the boiler is dispensed with, since the fuel is highly inflammable and burns without a residue of any moment. If the carbureter is not suitably designed several things may transpire,

- (a) The mixture may be so slow burning as not to be of value.
- (b) The mixture may be so impregnated with liquid fuel as to be very inefficient.

The slow burning feature may be due to excess gasoline, or the amount of gasoline intermingled may be less than the desirable quantity, and the flame propagation will be retarded on that account. These considerations are all assuming the motor is of suitable design and in good order; since the compression materially effects the rate of propagation of the flame.

The carbureter alone is not responsible for all the ills of inefficient work, since if the timing of the spark is not right the combustion may be late or early and the effect of the energy will be to no purpose. The discussion here, however, is on the assumption that all such matters will be given their due measure of attention and that the carbureter is in the position to perform its functions if the same is suitably designed and properly adjusted.

#### Why and Wherefore of the Carbureter.

It will not be possible to illustrate the various constructional features of carbureters now on the market, as it would require at least a volume of good thickness to make room for them; nor will any attempt be made to set forth the unusual virtues of any one scheme of design. Considering the float feed type of carbureter as the type most in use, its general characteristics will be set down, and an attempt will be made to point out the most likely causes of failure to work.

Fig. 1 shows an example of the type under discussion, the gasoline connection being made fast at the under side of the float bowl, the fuel flowing in through a filter. The filter consists of a cylinder or tube, perforated with small holes, and recessed, so that the forty-mesh copper gauze wrapped around the tube will not press closely over the tube and quickly grow a jelly like obstruction. The tube is screwed into place and can be removed at will, thus rendering its removal a matter of but a moment's time on occasions when to clean the filter becomes a necessity. There are carbureters not provided with any means for filtering the liquid fuel and the absence of the same is much to be deplored. The fuel passes through the filter, thence to the float bowl and the buoyancy of the float is called into play to press the needle of the valve into place to stop the flow of the gasoline when the liquid reaches a level 1-8 inch below the top of the nozzle.

The valve will work if the needle is of German silver, suitably pointed, and ground into a hole of suitable diameter, provided the metal of the seat is also German silver. If the seat is of aluminum it will give trouble within a short space of time, and in the author's opinion steel is not suitable for either the seat or the needle; German silver will do. Obviously the valve, if it leaks, will allow the gasoline to ooze by and the spillage will be a matter of grave moment, since the loss of fuel will go on continuously and the mixture will be most imperfect. On the other hand, if the float is not set at the right level the supply will be either scant or the fuel will continuously overflow the nozzle, to the great detriment of the quality of the mixture and at a loss of fuel not to be tolerated.

It was said the fuel should stand in the nozzle to a height 1-8 inch below the top; to be accurate, the level should be such that the liquid should form a bubble to be blown off at will, and the exact height should be found by this method. To be able to go through this form it is essential to so design carbureters as to render the performance possible. Since the nozzle has a very small hole, even for the largest automobile motors, the orifice is easily stopped up, and the construction should be such as to enable one to remove the nozzle for purposes of cleaning, without much trouble. The nozzle shown in the carbureter, Fig. 1, not only screws into place, but it is provided with a "tip," thus enabling one to readily change the sizes of the orifice should the occasion demand.

This brings us to another point that is of more than passing moment, since some carbureters are provided with needle valve nozzles, with a view to adjusting the size of the orifice at will. The author has tried out this scheme on his own car at considerable length (over two years), only to find that it serves no useful purpose at all. As a matter of fact, the needle in the nozzle does some harm, in that it eliminates the true nozzle effect, which is something to take into account. The size of the orifice, in any given case, is a constant. Small is the value, then, of any means of changing the adjustment of the nozzle, since there is no ground on which to explain the necessity of doing so; whereas the needle in the nozzle is prone to give trouble in that it is likely to back out and in doing so alter the supply of fuel to the entire discontent of the autoist.

In some carbureters multiple nozzles are used, and it is possible they answer some useful purpose, but very good results are attained with one nozzle only, and simplicity surely is worth something. Presumably very large motors would require multiple nozzles, but automobile motors are not large enough to demand more fuel than can flow through a single nozzle. The sizes of the orifice range between the openings represented by drills from number .48 to 60, although it is a very small motor taking only a 60 drill opening in the nozzle. The fuel density settles the question of the level of the float, and if the specific gravity of the fuel changes, the level of the float will change also, thus making it necessary to do something about it. In the carbureter illustrated in Fig. 1 this matter can be taken care of

in a very simple way, since both the float level and the nozzle can be adjusted to suit the specific gravity of the fuel. In carbureters not provided with adjustments it is necessary to dismount them to the extent necessary to change the adjustment and bring about a balance of the levels.

Alcohol, for illustration, is not of the same weight per unit volume as gasoline, and, for that matter, the latter fuel varies in weight from time to time. At the present time gasoline has a specific gravity of about 68° Baumé (Baumé scale lighter than water), whereas not long ago the gasoline ran about 72° Baumé. Motors adjusted for the lighter fuel would scarcely perform as well under the circumstances. The float sometimes gives annoyance from other causes, as, for illustration, if the float is of cork it is prone to get loggy, and if it does it will sink to a lower level, to remain until removed, dried and shellacked.

Cork is not necessarily the best material for a float, but a well-made cork float is better than a poorly-made copper float, since the cork will work a little when loggy, whereas the copper float will not work at all, after it springs a leak. Of course, there is no good reason why the copper float should be improperly made, but they are sometimes. At all events, if the fuel is not under good control there is a reason, and that reason must be located and the trouble removed ere any good work can be expected of the motor. The troubles are the following:

- (a) The float may not be at the required level.
- (b) The nozzle may be too high.
- (c) The nozzle may be too low.
- (d) The orifice may be too large.
- (e) The nozzle may be too small.
- (f) The filter may be stopped up.
- (g) The needle valve may be leaky.
- (h) The float may be loggy.
- (i) The float may have sprung a leak.
- (j) The counter-weights may be stuck.
- (k) The passage ways may be plugged up.
- (l) The nozzle may be plugged up.
- (m) The pressure may be off the carbureter.
- (n) The pressure may be in excess.
- (o) The piping may be plugged up.
- (p) The gasoline may be gone.
- (r) The gasoline may be of an inferior grade.
- (s) There may be an accumulation of water.
- (t) The hot air passage may be defective.
- (u) The depression chamber may be defective.
- (v) The cold air may not be properly regulated.
- (w) There may be a leak in the mixture manifold.
- (x) The mixture may be impoverished.
- (y) The mixture may be too rich.
- (z) The carbureter may not be suitable for the motor, at all.

The previous history is always important in a matter of this sort, as, for illustration, if a carbureter has been doing good work it is safe to assume it will do so again if the trouble is sought out, found and eradicated.

(To be continued.)

### WHY SOME ALUMINUM CASTINGS CRACK.

The most frequent source of the cracking of aluminum castings is caused by over-heating, or "burning," the aluminum while melted, says *The Brass World*. The demand for aluminum castings has now become so large, and many of them are so thin and complicated, that foundries continually have trouble in making them. The aluminum alloy most generally used for casting is one which contains aluminum and zinc. The presence of the zinc renders the casting difficult and far more liable to crack than when not used. Brass must be employed to obtain the highest strength. There are several rules that must be firmly obeyed in making aluminum castings, and they are: To melt the aluminum with a slow fire, so that the top of the metal will not become "burnt" before the remainder of the metal is melted; to avoid overheating the metal after it has once melted, and pack the ingots in the crucible as compactly as possible, so that portions will not stick up and become exposed to the action of the flame. Do not have the aluminum melted before the mould is ready, as this is a common source of trouble.

## ECONOMY OF TWO AUTOMOBILE OWNERS

IF some of the stories that have been told of the expense of keeping an automobile were to be implicitly believed the average man might just as well throw up his hands at the outset and wisely conclude that automobiles, like steam yachts, were purely the pastime of the millionaire. But there is another side to the story, and equally great extremes have been reached in this direction as well. If some of these stories could be regarded as gospel, there would be small reason why the average parent could not present his ten-year-old with a machine, confidently expecting that his pocket money would be sufficient to maintain it on.

But they are the two extremes that make the prospective purchaser doubt either, though both are true. Between them there are literally thousands of autoists whose expense accounts do not reach either extreme. They get a large mileage and a great deal of pleasure out of their cars, and their expense accounts show why. Two of these are appended, and they speak for themselves.

### THIS VERMONTER RUNS HIS OWN CAR.

Editor THE AUTOMOBILE:

I have noticed several statements from different subscribers regarding the expense of owning an automobile, and just for fun I will add mine to the list. I will say, to begin with, that if it cost me anywhere near as much as the man who told his story in the December 12 issue I would not run one at all. I have been running for two years a 16-horsepower four-cylinder car, weighing 1,900 pounds, and when I got it there was no odometer on it, but October 13 last I got a small one for \$7.50 and mounted it on the steering knuckle. It is a Veeder and accurate. I have run almost 4,300 miles since putting it on, and I am sure I ran at least 2,700 miles before, making 7,000 miles in two years.

Like the man from California, I am something of a mechanic and I take care of the car and no one else runs it. I have had but two nail punctures, one of which I repaired and the other was repaired at a public garage and the charge was \$1.25, this being my total tire expense to date.

I average twenty miles to the gallon of gasoline and on long runs more, often reaching twenty-four miles and occasionally as far as twenty-four and six-tenths miles, and there are no State roads here, although they would probably be classed as "fair" dirt roads and rather hilly.

Last spring I exchanged my storage battery for a new one and paid the makers \$12.63 for the exchange, so I don't put this in the list, and it costs me nothing to recharge it, and even if it did the expense would not be \$10 for the entire mileage. Gasoline costs by the barrel from 14 to 16 cents per gallon. This is my expense account:

Tire casings .....	none
Inner tubes .....	none
Repairs to tires .....	\$1.25
Anti-skid devices (tire chains).....	10.00
Power (gasoline) .....	48.81
Oil and grease.....	18.80
Ignition .....	.20
Spark plugs .....	none
(Never injured one in my life.)	
Repairs, new chain.....	7.98
Repairs, fan belting.....	.72
Repairs, estimated .....	7.00
(This is repairing broken spring and reverse gear band recently, and bill not yet rendered.)	
Repairs, due to accident.....	2.75
(Broke my top.)	
Lights, carbide .....	4.40
Cleaning waste .....	none
(I patronize my wife's ragbag.)	
Sponges, chamols, etc.....	2.50
Garage rent .....	none
(I keep it at home.)	
Total.....	\$104.41

This is about 1 1-2 cents per mile. My tires are in pretty good condition now, although I expect next year to have some expense in this direction.

If anyone doubts any statements I have made, I stand ready to back them up with a ride next summer of a hundred miles and wager two to one that I won't use five gallons of gasoline.

BRATTLEBORO, Vt.

C. A. S.

### A BAY STATER WHO RUNS A TWO-CYLINDER.

Editor THE AUTOMOBILE:

We were interested in the expense account of the San Francisco autoist (13 1-2 cents a mile for a \$2,500 four-cylinder touring car) as given in letter No. 1016, in a recent issue of your paper, inasmuch as we have run a two-cylinder touring car all this season at an expense of 4 1-5 cents a mile and had begun to think something of a four-cylinder for next season.

We are not machinists and, in fact, had no idea at all as to what it was that made automobiles go (or stop, for that matter), but, nevertheless, May 1 we took a chance on a new two-cylinder touring car, 22-horsepower, double opposed motor, planetary transmission and chain drive, and with top, odometer, extra casing and tube, and attachments, yard gasoline tank, and a few garage supplies, it set us back just \$1,475 before we got under way. We have run the car to date 5,200 miles (in five different States) and our expenses have been as follows:

Feed (gasoline, oil, batteries, carbide for lamps, etc.) .....	\$85	.01 6-10
Tires (casings, tubes, valves, cement, sleeves, etc.) .....	70	.01 4-10
Repairs (mostly petty adjustments).....	30	.00 5-10
Miscellaneous (storage, washing, etc., on tours, extra tools, parts).....	40	.00 7-10
	\$225	.04 1-5

We have taken care of the car ourselves and have kept it in our stable. We have averaged seventeen miles on a gallon of gasoline, and seventeen miles an hour on the road (and thirty-five to forty on good bits of road); the longest day's run has been 157 miles (Pittsfield to Boston); we covered 4,000 miles before we had any tire trouble.

People have told us that the car took the hills as well as a well-advertised four-cylinder hill-climber, costing over \$3,000 with extras, and that it made no more noise than this car.

We do not cite the above as anything exceptional, but as we consider these facts we have come to the conclusion to let well enough alone, inasmuch as our two-cylinder car has proved reliable and economical, with all the power all the time that anyone could ask for. The car runs as well to-day as it ever did. What more do you want?

DORCHESTER, MASS.

G. H. E.

### SOME ESSENTIALS OF ACCESSIBILITY.

We consider the following should be the minimum standard of accessibility in any high-class car, says *Engineering*:

(1) The bottom half of the crankcase should be removable without touching the dust-screen or any pipes or fittings; (2) the clutch should be removable without disturbing the engine, gear box, or any other parts except the immediate connections to the clutch pedal; (3) the gears should all be removable from the gear box without taking this out of the car or disturbing the change-speed levers; (4) it should be possible to remove the bevel pinion and crown wheel of the back axle without taking the weight off the road wheels, and it should be possible to see these wheels running in place.

## LETTERS INTERESTING AND INSTRUCTIVE

### LUBRICATING VALVE STEMS OF MOTORS.

Editor THE AUTOMOBILE:

[1,035.]—In your answer to my query, No. 992, in your columns, you have evidently misunderstood the question. You explained oiling of the push rods by splash, etc.; this, of course, has nothing to do with the valve stems where they pass through the wall of the combustion chamber. Not only is there no provision made for lubricating valve stems, but it is well nigh impossible for the driver of a car to apply any oil to a valve stem in the usual type of vertical motor, owing to a closely wound valve spring surrounding the valve stem and this spring resting against the under side of the combustion chamber, thus preventing one from reaching the valve stem with an oil can.

Can you explain why the water boils in a motor having a properly designed cooling system and said system being in good working order? I am well aware of the causes usually assigned, such as "a retarded spark," "too rich a mixture," "carbon in the cylinders," etc. This, however, does not explain why the water boils. For example, with a retarded spark the burned gases are in the cylinders for a shorter interval than with an early spark. It would seem, therefore, that we should have boiling of the water with an early spark, rather than with a retarded spark.

Minneapolis, Minn.

O. A. WEISS.

We have never had a case come to our attention where it was necessary to oil this part of the car, and as practically every car on the market that has a vertical motor is lacking in such provision it would not seem that there is any great necessity for it. Should you find that the motor of your car will not work well unless the valve stems are lubricated, take out the plugs over the valves and then turn the motor over slowly until the first valve is fully open. This should give an opportunity to introduce the desired oil on the stem; treat each one in the same manner. We doubt, however, whether this will be found to make any great improvement in the running of the motor.

The water boils because it has reached a temperature of 212 degrees F., and this is because its surroundings are at a still higher temperature. Are you not assuming too much in a "properly designed cooling system in good working order?" If it fulfills these conditions there is nothing wrong with it and the water should not boil away. The various reasons you assign do explain *why* the water boils, because they explain why the temperature becomes so much higher than it should under normal conditions and with everything in good working order. Your assumption regarding the retarded spark is somewhat erroneous. With a properly timed spark the explosion has occurred and utilized most of its force before the exhaust valve opens; it has expended its heat in driving the piston. When fired late the explosion is practically at its height when the exhaust begins to open, so that instead of spent gases issuing, live, hot flames are exhausted, as may be noted by removing the exhaust manifold. Moreover, the explosion has taken place at reduced compression owing to the delay; the speed of the motor is likewise reduced, and this affects the movement of the gases in the same manner, so that instead of clearing the combustion chamber of the burnt charge some of it is penned in there, still burning, or at least at a very much higher temperature than if the explosion had been normal, in which case there would be little or none left.

### A FIVE-TON TRUCK FOR COUNTRY ROADS.

Editor THE AUTOMOBILE:

[1,036.]—Will you kindly let me know the names of concerns manufacturing motor trucks of five-ton or more capacity? We are in the market for a large truck to be used on country roads, and should be pleased to hear from manufacturers of above vehicles. Have steel wheels been used, and are they a success?

New York City.

M. STROUSE.

You will find several manufacturers of commercial vehicles run announcements of their products in our advertising pages. Better communicate with them direct, stating your requirements. Steel wheels have not been used thus far to any extent.

### IS A MASTER VIBRATOR NECESSARY HERE?

Editor THE AUTOMOBILE:

[1,037.]—I am a constant reader of "The Automobile," and especially "Letters Interesting and Instructive." Would you kindly give me a little information on the following subject? I have made an automatic governor attached to an "Apple" dynamo, which will keep the dynamo at a speed I may adjust it for, independent of the speed of the engine, no matter how quick the engine may change from fast to slow, or vice versa. I have a lamp connected to the machine which gives a steady light. I wish to take current from the dynamo to a four-unit Splitdorf coil. Would it be necessary to use a master vibrator? If so, on what principle is the vibrator made?

ARTHUR BEIJER.

Worcester, Mass.

If, as indicated by the steadiness with which your light burns, there is no excessive fluctuation of the voltage of the current generated by the dynamo, regardless of the speed of the engine, there appears to be no reason why the ignition system should not be run directly from it. Connect the dynamo to the low-tension timer, the same as if it were a battery. No master vibrator is necessary merely because a dynamo is employed instead of some other source of current, nor does a master vibrator, so-called, differ from any standard device of the kind. Its title arises from the fact that it is employed to time the action of all four coils and works independently of them. It is nothing more or less than a fifth coil of the vibrator type, the action of which successively sets in operation four others of the non-vibrating type. The object is to render the firing more uniform by overcoming the difficulty of adjusting four vibrators so that they will work exactly alike.

### SHORT FOCUS LAMP REFLECTORS.

Editor THE AUTOMOBILE:

[1,038.]—What is the advantage of "short focus" lens mirror automobile lamps, and is not the supposed merit in such design purely on advertising "talking point"? It seems to me that, so far from its being an advantage, it is a positive disadvantage, in that the placing the flame so near the lens simply increases the dangers of breakage, sooting, etc. So long as you have a given diameter of reflector, with consequent similar diameter of beam, of what possible advantage can it be to get the lamp so close to the reflector as some lamp makers seem to approve. Another point—why is a large diameter reflector materially better than one of the small diameter? If the small one catches practically all the light, the large one cannot do much more, for the difference in the diameter of the beam is not noticeable after the first few feet because of diffusion, etc.

A. WALTER REED.

Bisbee, Ariz.

The merit of the short-focus lens-mirror reflector is anything but a mere talking point, since it is a fundamental principle of scientific lamp design to secure a maximum intensity of illumination. Any source of light emits its rays in every direction, consequently the light falling on the interior of a sphere is the total amount emitted. And, obviously, the smaller the surface upon which this total amount is concentrated, the greater the intensity of the illumination per unit of area. Therefore, the smaller the sphere the brighter its inside is illuminated. This being the case, it must be equally true of any part of the interior of the sphere, or of any non-spherical surface occupying a corresponding space. So, if a reflector be placed six inches, on an average, from a source of light, it receives approximately the same intensity of illumination as would a twelve-inch sphere. On the other hand, to illustrate by taking an extreme case, a reflector six feet away from the light will receive only the same illumination as would a twelve-foot sphere—only 1/144 as much, since the surfaces of spheres are in proportion to the squares of their diameters. As for the size of the reflector, it is clear that the closeness of the flame, or shortness of the focus, which is the same thing, is limited to some practical minimum by the considerations you mention—sooting

and heating. The result is that the larger the mirror that can be placed at the given distance the more it will intercept of the light that otherwise would fall on the interior of a surrounding sphere. Practically, however, there are limits to the advantage to be gained by going to extremes in this direction, for to make the beam too large would simply reduce its intensity. Also, with a reflector wholly behind the light, no matter how large it were made, it must still continue to intercept less than half of the spherical illumination. This consideration accounts for many of the extreme parabolic reflector surfaces, extending even forward of the vertical plane in which their focus—and the light—is found. The light that is radiated forward from the flame is another worry of the lamp designer. Left to itself, this portion of the illumination naturally diverges radially with the corresponding rapid drop in areal intensity. So transparent glass lenses are placed in front of the flame in some lamps to bring the diverging rays at this point into parallel forward lines.

#### MISSING DUE TO LEAKY EXHAUST VALVES.

Editor THE AUTOMOBILE:

[1,039.]—I saw my answer in to-day's "Automobile," and thank you for it and advice. I am sending you a new diagram of my car. The two cylinders are cast together, the intake is on the top of cylinders, and the exhaust is on the side, directly under the intake. I have to take my intake valves out first to get the exhaust valves out the same hole. I made a mistake in saying I used a 1-2-inch pipe. I am using one-inch standard galvanized pipe (iron). My intake manifold is held on by a bolt running through the center of it. I use a gravity feed gas tank in the rear of my car about 4 or 5 inches above the carbureter. Could a manifold be made to do for this outfit? I have suction intake valves. Cylinders are about 3 3/8 by 3 3/8 inches square. I have not ground my exhaust valves for about one year, and have used the car on an average of 100 miles weekly. Have I let them go too long? Car runs good, only in last two weeks it has skipped fire a great deal. I took the coil to the makers and they said it was O.K. I have tested the plugs, and they are O.K. Battery O.K. Would the valves (exhaust) not being ground for so long cause it to miss fire? My intake valves have done a lot of popping and are noisy here lately. They used to run silently before. Would poor springs cause that?

New York City.

F. C. FRANKS.

There is no reason why a manifold could not be made to fit the motor in question. It is very poor practice to obstruct a manifold, and particularly the inlet, by running a bolt through it in the fashion you mention, as it tends to cause wire-drawing of the incoming charge, thus reducing the power of the motor. There is no set rule for regrinding exhaust valves, but it would certainly seem well to do so at the end of 5,000 miles' running, while at the end of every 1,500 to 2,000 miles would probably be better. Leaky valves would be responsible for missing, as considerable of the charge could be driven out through them on the compression stroke, so that there would not be enough left in the cylinder to fire. If you have done 5,000 miles with your car in steady service, it is hardly too much to recommend giving the motor a thorough overhauling, and doubtless you will find a number of things that need remedying, which later would mean replacements.

#### CAUSES AND REMEDIES FOR OVERHEATING.

Editor THE AUTOMOBILE:

[1,040.]—I have a four-cylinder St. Louis touring car which does very well in all respects, except the motor heats, so much as to boil the water in the radiator, after going only a few miles. I have examined it and have come to the conclusion that the radiator is foul. I am going to ask what do you think about it; also, what solution can I put into the radiator to clean it out? I don't think the radiator is greasy, but a deposit of some kind from the water.

Bridgeport, Cal.

SUBSCRIBER.

The fouling of the radiator will cause the motor to overheat, but other adverse conditions, such as improperly timed valves, an over-rich mixture, clogged circulating system and a number of others that will suggest themselves upon reflection. If the radiator shows deposits of hard material from the water it is better to take it down and subject it to a thorough cleansing with the aid of a pickling solution. This consists of 90 per cent.

water and 10 per cent. sulphuric acid, or commercial vitriol. This solution is both poisonous and corrosive, and care must be used to prevent having the hands or clothing come in contact with it. The action of the solution may be increased by heating in case the deposit does not yield to it readily. The progress of the cleaning should be watched, preferably by drawing off the contents of the radiator, and renewing the solution from time to time. When the operation is complete the radiator must be very thoroughly flushed out, soft water being used, if possible, as it is the hard water you have been using that causes the trouble. Examine the water jackets and give them the same treatment, if necessary; also investigate the carbureter and valves, and it should not be difficult to remedy the trouble.

#### EVERY AUTOIST MUST ANSWER FOR HIMSELF.

Editor THE AUTOMOBILE:

[1,041.]—What is the formula adopted by the A. L. A. M. for computing the horsepower of motor in an automobile? I have concluded to buy a 1908 Pope-Hartford. I was undecided between it and the Light Six Stevens-Duryea. I want to ask you if the latter is as much better than the other sixes as the manufacturers claim on account of the three-point suspension? What is the value of this method of suspension? If it is so wonderful, why don't others adopt it? Do you think the six-cylinder car is superior to the four-cylinder, and will in time supersede it? Do you think there is \$750 difference in value between the Light Six Stevens-Duryea and Model M Pope-Hartford? Do you think I have made a wise purchase for the price?

A. I. GAMMON.

Pasadena, Cal.

The formula is  $\frac{D^2 \times N}{2.5} = \text{HP.}$ , in which  $D$  is the bore of the cylinder;  $N$  the number of cylinders of the motor, the denominator representing a constant which is said to have been figured from a voluminous amount of data on the performance of a great many standard American motors; though, as a matter of fact, it is practically identical with that adopted by the Royal Automobile Club of Great Britain. We had flattered ourselves that this information had been published in THE AUTOMOBILE a sufficient number of times to have come to the attention of every reader, but this does not seem to be the case.

Concerning the remainder of your queries, these are something that every autoist finds he must answer for himself, as they are so largely a matter of personal opinion. Every manufacturer naturally proclaims his own wares the best the world has ever seen and can always write a brief to substantiate his claims. The advantages of the three-point suspension are that it permits the use of a unit power plant and transmission, so supported as to be proof against any torsional strains of the frame, or other parts of the car. It is employed by several makers, while others attain the same end in a different manner. We can hardly reopen the six-cylinder matter here, and would refer you to the numerous articles and editorials on the subject that have appeared in the past half year or more in these columns. With anything except money itself, value is inevitably a matter of personal opinion, and something in the shape of a car that might strike you as hardly being worth the expense of towing it to the scrap heap might be a gem in someone else's estimation. We think you have made a wise purchase and will feel satisfied that your investment represents every dollar it cost you.

#### THE "DRAW-BAR PULL" OF AN AUTOMOBILE.

Editor THE AUTOMOBILE:

[1,042.]—How great is the pull, in pounds, exerted by the average automobile? That is, if the machine were tied to something so as to tow it, how many pounds would a spring balance show in the tow line? And what is the similar towing power of a good horse?

Garden City, L. I.

IRVING BRENNERMAN.

With plain pneumatic tires on ordinary level road surfaces automobiles of ordinary size and horsepower will give "draw-bar pulls" ranging from 200 to 500 pounds. Most automobile engines, working through the lower gears, would give much higher pulls if the tractive adherence would permit, so with

very heavy vehicle weights, and with non-skidding tire treads, pulls greatly in excess of the figures given can be obtained. An ordinary horse, which is capable of exerting several horsepower for brief periods, can pull as much as 400 pounds under favorable conditions—very slowly and with suitable harness. But as it cannot maintain such strength of pull very long, nor at all at any speed, the immensely greater speed, hauling capacity and power requirement of the automobile, without materially higher pull, is readily perceived.

#### WHAT IS THE EFFICIENCY OF 4-WHEEL DRIVES?

Editor THE AUTOMOBILE:

[1,043.]—Will you kindly give me, through "The Automobile," any information available in regard to the construction of the most promising mechanical four-wheel drives with which you may be familiar? I am not certain that any successful drive of this kind has ever been brought out. Do you think there is any great advantage in driving through all four wheels, and would it not be offset by added complication in the wearing parts of the machine?  
Cleveland, Ohio.

H. B. H.

So far as our knowledge extends at present, we believe the only practical four-wheel drive on the market that has been in use for any length of time is the "Couple-Gear" electric. In this the motor is self-contained in each wheel, so that each is an independent unit. There have been several others in the past, notably one made in Milwaukee, in which a gasoline engine was employed and the power transmitted to the four wheels by mechanical means, but whether its failure was due to technical or financial reasons we do not know. There is an advantage in driving all four wheels for commercial work, where speeds are low and loads are heavy, and whether or not this is offset by the extra complication will naturally depend on the extent of the latter. There would certainly be no object in employing a four-wheel drive on a pleasure car.

#### HAVE SOLDERED JACKETS EVER BEEN USED?

Editor THE AUTOMOBILE:

[1,044.]—I would like to ask you, through the columns of your valuable paper, if any manufacturer has ever tried soldering copper jackets to the cylinder castings. I have a small double-cylinder engine which I built myself. The copper jackets are soldered onto the flanges, and during the six months it has run it has never caused a particle of trouble. The slight expansion of the copper on being heated has never caused them to leak, and they are as solid as the day I put them on.  
Peru, Ind.

E. SPARENBERG.

Not to our knowledge. Elaborate precautions are always taken to insure the jacket staying in place, and it is usually calked on with a soft steel or copper ring pressed into a groove with the end of the jacket, under great pressure. Many of these jackets are seamless and thus require no soldering at all, while on others solder is merely employed to reinforce the mechanical joint in the copper and make it absolutely water tight. You do not mention for what purpose your motor has been employed, but if it has been mounted on a car we must certainly commend the manner in which the soldering has been done, as the inflexibility of such a joint and the readiness with which it gives way to vibration or slight shocks constitute its chief weakness and make it a poor thing to have on an automobile.

#### EXPLAINING THE DEFECTION OF CONE CLUTCH.

Editor THE AUTOMOBILE:

[1,045.]—I am about to place the following mixture in the radiator of my machine, and would like to know if it will be as effective as an anti-freezing solution in climates such as we usually have in New York during the winter.

Twenty-five per cent. glycerine.

Twenty-five per cent. wood alcohol.

Fifty per cent. water.

My machine is fitted with the common leather-faced cone clutch. The engagement is always accompanied with a great deal of vibration, to overcome which I have used caetor oil liberally, but without success. The clutch is neither too light nor too loose, neither is the

leather worn or cut, and the vibration occurs if it is let in fast or slow. Any remedy you can suggest will be appreciated.

Weet New Brighton, S. I.

A. L. HENRY.

The solution you refer to should be able to withstand the greatest extremes of cold experienced in the vicinity of New York City, as a 25 per cent. solution of glycerine and water freezes at 5 degrees Fahrenheit, and the same strength of solution using wood alcohol resists freezing down to zero Fahrenheit, from which it will be evident that your proportions are unnecessarily high and could be considerably reduced with a great saving in the cost of the solution, and without lowering the factor of safety unduly.

With reference to the clutch, the fact that its engagement always sets up a great deal of vibration would seem to indicate that there is a lack of alignment between the crankshaft and the clutchshaft, the vibration being the result of their struggle to accommodate themselves to one another when forced into engagement. This may be caused by the clutchshaft being bent, or by its having been forced out of correct alignment in some other way. Raise the footboards of the car and watch the action of the clutch as it is let in and the defect will be apparent. The remedy is obvious.

#### HOW CAN CYLINDERS BEST BE CLEANED?

Editor THE AUTOMOBILE:

[1,046.]—Will you please inform me, through "Letters Interesting and Instructive," the best way to get carbon deposits out of cylinders, without dismantling the engine? Also, should the timer be packed in hard oil?

W. I. H.

Waterloo, Iowa.

This will depend upon the accessibility of the piston heads as well as on their condition. Carbon deposits are sometimes so hard that nothing short of dismantling the engine will suffice, and even then it is no little work to remove them. A solution consisting of hot water and washing soda is said to be efficient for loosening the deposits, also kerosene and gasoline, while special chemical compounds are also said to be on the market for this purpose, but we do not know anything of their value. If the deposit be a troublesome one of long standing, unless every part of the piston head can be reached with a scraper from the outside, it will be absolutely necessary to take the motor down. This will depend upon the type of timer used on your car. Many makers recommend that their timers be packed with grease, especially where they are of the ball contact type.

#### NEVER DROVE A 200-H.P. CAR IN VANDERBILT.

Editor THE AUTOMOBILE:

[1,047.]—I wish you would settle a dispute for me by answering the following questions: Did the French driver, Hemery, driving a 200-horsepower Darracq, win a Vanderbilt race one year? And if so, what year?

ROBERT M. CUNNINGHAM.

Lyndon, Ky.

Hemery won the 1905 Vanderbilt Cup race, driving an 80-horsepower Darracq—at least that was the nominal rating of the car, though its actual power was much greater. Later he drove the eight-cylinder, 200-horsepower Darracq on the Florida beach course once, and was then disbarred for insubordination by the officials, Demogeot then taking the car and making the famous record of 122.44 miles an hour with it. There has never been such a high-powered car as this driven in the Vanderbilt race, and it is doubtful if so much power could be used to advantage on a road course.

#### INFORMATION WANTED ON SELF-STARTERS.

Editor THE AUTOMOBILE:

[1,048.]—Could you inform me where I can get the best information concerning methods and devices for the self-starting of gas engines, and also tell me that number of last year's "Automobile" which contained an account of the contest held in France on this subject (Methode and Devices for Self-Starting). I believe that certain of the devices were explained in that issue.

Golden, Col.

D. B. DOYLE.

The contest in question was held in connection with the Paris Salon of 1905, and the prize was granted to the Mors for a

somewhat complicated device employing a second carbureter, a hand pump and a distributing valve. If you have access to the file of *THE AUTOMOBILE* you will find a description of the more prominent devices in one of the issues of the latter part of December, 1905, but as the number in question is out of print we could not supply it. If there are any works on the subject that our readers know of, we should be pleased to bring them to the attention of the inquirer.

### CONCERNING THE QUESTION OF TIRE REPAIRS.

Editor *THE AUTOMOBILE*:

[1,049.]—Being a subscriber to "The Automobile," I am taking the liberty of writing you for information.

The tires of my Reo touring car have been used for two seasons, but they have never been punctured and have consequently never been run flat. However, the tread is practically worthless, and I write to inquire if it will do to put new treading on the old canvas. That is, would you expect the old canvas to be good enough to pay for retreading?

J. G. TURNBULL.

Barton Landing, Vt.

Unless the tires have been run so long with worn treads that the canvas also has worn, or rotted through becoming wet frequently, it is decidedly advisable to have them retreaded, as it is not uncommon for the same fabric to stand retreading twice and in some cases three times. Unless there is a good tire-repairing establishment convenient, it is best to return them to the makers for repairs, and the latter will seldom fail to advise you whether the tires are worth repairing or not, as a retreading job that would give way in a few hundred miles would not add to the reputation of their repair department.

### ABOUT RECHARGING DRY BATTERIES.

Editor *THE AUTOMOBILE*:

[1,050.]—Can dry cell batteries be recharged with a magneto? If so, which would be the best way of wiring? DRY CELL.

Port Hope, Mich.

Dry cells cannot be recharged by a magneto, nor in any other way so as to give a practical return for the amount of current sent into them. A magneto generates an alternating current, which consequently cannot be used for charging without converting it into a direct current. When the latter is sent through an apparently exhausted dry cell for a length of time the cell will show signs of recuperation, but the result is of so little value that the possibility of recharging such a cell is really confined to the realm of laboratory experiments. When dry cells are actually exhausted there is no alternative but to replace them.

### REPAIR PARTS WANTED FOR AN OLD STEAMER.

Editor *THE AUTOMOBILE*:

[1,051.]—Will you please be kind enough to inform me where I can get repairs for the steam engine of the Mobile steamer, also what is, in your judgment, the best compound to put in a fire tube boiler to remove the scale? H. A. MERTEN.

Des Moines, Ia.

There is a concern whose announcement you will find in our advertising pages who make steam specialties for automobiles, and while we hardly believe that they make replacement parts for the car you mention, they may be able to meet your requirements. There are numerous special compounds on the market for this purpose which can be had ready to use.

### SOME FIGURES REGARDING COST OF IGNITION.

Editor *THE AUTOMOBILE*:

[1,052.]—Why is it that some of the dry battery manufacturers are not more alive to their opportunity in connection with automobile ignition? A set of six dry batteries of ordinary size costs \$1.50 at the garage, and lasts in ordinary service not more than 600 miles, probably less. If one drives his car 6,000 miles in a season, which is less than many motorists do, he pays \$15 for batteries alone; the chances are that he will actually pay more. If he has a fairly economical engine, his gasoline will cost him 1 cent to 1.4 cents per mile, and his season's bill will be \$60 to \$75. In other words, his batteries cost him about a quarter as much as his gasoline. Yet all that the batteries have to do is to ignite the mixture, which requires a hardly measurable amount of energy. Fifteen dollars a year is 5 per cent. of \$300, from which it would

at first seem cheaper to use a magneto costing from \$150 to \$200. But magnetos wear out, like anything else about a car, and I am told that when their gears become worn they are very noisy. Anyway, it is a lot simpler and cheaper to throw away an exhausted set of batteries than to repair the magneto that has got out of order, so it would seem that for economy the batteries have the best of the argument. The worst thing about the dry battery is its small capacity and the fact that it dries out when not in use. I understand that there is a battery made somewhere which is claimed not to dry out as fast as the ordinary kind. Do you know what it is? If one concern can make such batteries, why cannot the others do it also? If they can, it will be worth while to make the batteries larger, so that the cost of renewal will be nominal. As matters stand, everybody seems to want the magneto, and batteries are getting the worst of it.

E. LEEDS POWELL.

New York City.

### HOW TO LENGTHEN A SMALL CAR'S WHEELBASE.

Editor *THE AUTOMOBILE*:

[1,053.]—In answer to inquiry No. 976, page 769, in "The Automobile" of November 21, I should like to state that the inquirer can lengthen the wheelbase of his Maxwell runabout very easily and at little expense. If done according to the following, the result will be most satisfactory. Take off the front spring forks and have them lengthened just ten inches by welding on drop forgings, of course maintaining the same curve; then bolt them in

METHOD OF LENGTHENING THE WHEELBASE OF A MAXWELL.

three places to frame, use the same springs, but get spring clips one inch shorter and have attached as per sketch. In most places the old holes can be used by fitting. Then cut the steering rod in the middle and have a piece brazed in three inches long. I attached a three-foot running board and made new mudguards, the front five feet long, and then fitted red leather aprons, so my car not only runs far easier, but is mud proof. If Maxwell desires any more information, I should be pleased to give it.

South Orange, N. J.

G. M. JEFFERY, JR.

### CAN ANY TOWN DISPUTE THIS HONOR?

Editor *THE AUTOMOBILE*:

[1,054.]—I have read from time to time of different small cities and towns that "brag" of their great number of automobiles for a place of their size, but I can't remember of ever reading anything concerning a city or town that has the least number of cars in proportion to their size. Frostburg, Md., I think, has anything beat to a standstill in the United States, for it is a town of over 8,000 inhabitants, and not one automobile owned or ever was owned in the town. How's that; can anyone beat it? They have good State roads leading to the east and south of them, one stretch of eleven miles of fine National pike road leads to Cumberland, Md.

Myersdale, Pa.

L. F. H.

### ENTHUSIASTICALLY BACKS MR. FAY'S VIEW.

Editor *THE AUTOMOBILE*:

[1,055.]—I wish to say that I thoroughly endorse every word of what George A. Fay, of Meriden, has to say, in your issue of November 28, regarding tours, and if you want to make your paper worth more than your new price, \$3.00 per year, just have some more articles similar to "The Thousand Miles of New England." published November 7.

Hartford, Conn.

SUBSCRIBER.

### LIKE TO HEAR FROM FORD MAGNETO USERS.

Editor *THE AUTOMOBILE*:

[1,056.]—I saw the answer to my battery question, No. 921, and thought that the drawing I marked No. 2 was the best one, as six batteries were wired for two coils, and six more for the other two cylinders. I have a Ford Model N which seems to use up batteries. Would like to hear from Ford users who have put on a magneto.

Warren, Mass.

LOWELL ELLIS.

DOUBLE FILE OF OUR STURDY AUTOMOBILE ANCESTORS AT PARIS SHOW.

THERE is one portion of the big exhibition on both sides of the River Seine at Paris where selling price and 1908 improvements are never mentioned—and it is by no means the least interesting section of the show. Ten years is not a long period in the life of most industries, but a decade in automobiling takes one back to a period when a handful of enthusiasts were undecided whether gasoline or steam should be used on the road, and when the great majority was totally indifferent to either.

In commemoration of the decennial, not exactly of the automobile industry, but of French automobile shows—the first one was held during June, 1898, in a tent in the Tuileries Garden—M. Ballif, president of the Touring Club, was entrusted with the work of gathering together a representative group of relics, to form a retrospective exhibition on lines similar to the cycle exhibition of last year. The two-wheelers failed to arouse much enthusiasm, probably because we have advanced too far to care for the uncertain march of a high boneshaker. It is different with the automobile; most of those who helped to put it in motion are still with us, lost too often in the huge crowd of newcomers, but always enthusiastic over their early experiences, and always listened to with interest when they relate their exploits.

Though there are four and six-cylinder engines built by Forest in 1888, magnetos and make-and-brake mechanism of the same period, not much attempt is made to trace the work of such earlier inventors as Beau de Rochas, Lenoir, and their contemporaries, the more active period from 1890 being dealt with more completely; Cugnot's three-wheel steamer, invented in 1770, appears to have been given a place beside some fifty more youthful companions because of it being the first self-propelled vehicle to travel over ordinary roads.

One of the earliest of steamers to be used successfully on the road is shown in a ponderous vehicle produced by Amédée Bollee, Sr., in 1878, at his small factory at Le Mans. It was in the same town that, seven years later, Henry Fournier served an apprenticeship in his father's machine shop, and still later introduced the first foreign motor bicycle into America. One of Serpollet's earliest attempts is shown in a small three-wheel steamer, built about 1889 in a small workshop in one of the populous quarters of Paris. It was not until about eight years later that Frank Gardner, an American citizen, joined Serpollet and formed one of the first automobile companies in the world. Serpollet died this year, just when he had reached the height of his ambition; Frank Gardner is still living in France.

#### How a Count and a Mechanic Struggled with Steamers.

De Dion's first attempts to solve the problem were in the form of steamers, the earliest being an 1886 wire-wheel tricycle

with more resemblance to a lawn sprinkler than an automobile. It is one of the romances of the industry how Comte de Dion, a pleasure-seeking young man-about-town, became interested in the automobile by seeing a small toy model offered for sale at a street stall in Paris. He inquired for the inventor and was introduced to Bouton, a working mechanic, whose factory formed part of his modest dwelling. The titled society man encouraged the Parisian workman, and later entered into business relations with him, much to the disgust of supercilious aristocratic relatives and friends. For several years De Dion-Bouton steamers competed with gasoline rivals until it was shown that the internal combustion type had the greater future, when a

change was made—not, however, before steam had defeated gasoline in a keenly contested struggle for speed supremacy.

Electric vehicles were never at any time greatly in favor in France, this doubtless accounting for only two of this type being shown, the more important being the *Jamais Contenté* with which Jenatton in 1899 first traveled a mile a minute. A Jeantaud electric is given a place of honor because it was used by Michelin to make his first experiments with pneumatic tires.

A full series of old timers is supplied by Panhard & Levassor, the earliest being a two-seater of 1891, driven by a single-cylinder Daimler motor. There is a touch of romance in the story of how Sarazin, a French engineer interested in the internal combustion motor invented by Gottlieb Daimler, presented it to Levassor, then associated with Panhard in an engineering establishment. When Sarazin died in 1887 he charged his wife to look closely after the business which had been commenced with Daimler. Two years later Daimler gave the sole representation of his engine to the widow of Sarazin, and a couple of months after Madame Sarazin became Madame Daimler. One of Daimler's vehicles, and the first one to be seen by Levassor on his visit to the Stuttgart factory, forms a part of the retrospective exhibition. As we now understand the word, it requires a stretch of the imagination to term an automobile the ponderous vehicle designed to run on rails. At that time the Daimler motor was transverse on the car, geared to the rear axle by transverse shafts. It was this feature that Levassor criticised and later

BOLLEE'S 1878 STEAMER CARRIED SPOKER IN THE REAR.

JENATZ'S "JAMAIS CONTENTE," WHICH DID FIRST MILE A MINUTE

improved by placing the motor in front and connecting up to the rear axle by a sliding gear transmission and single chain.

Madame Levassor maintained a deep interest in the work of her husband and rode with him on the first successful trip from the factory to the Point du Jour—not more than ten miles—one of the incidents of the journey being a stop to visit Bollée, who was repairing his steamer at a blacksmith's shop.

#### Relics of the World's First Automobile Race.

Several survivors of the world's first automobile race, organized in June, 1894, by the *Petit Journal*, from Paris to Rouen, a distance of about eighty miles, are placed on exhibition. Levassor won, followed by a Peugeot, other competitors being a De Dion steamer and a Scotte steamer. The first of the Peugeot team figures side by side with the winner, thirteen years after they noisily struggled for supremacy on the highway. It is claimed for the Peugeot that it is the first automobile to be built in France, for it was constructed on Daimler's model before Levassor had produced his car with motor in front and sliding gear transmission. At that time Peugeot obtained his Daimler motor from Panhard & Levassor, but when Levassor produced the Phoenix engine Peugeot shook off the dependence on a rival firm by designing a horizontal motor of his own.

Plenty of material is to be found in the exhibition to recall memories of the Paris-Bordeaux and return race run in the June of the following year, and also won by Levassor, at an average speed of 24 miles an hour. The *Petit Journal* refused to organize another race, and a committee was formed, which later developed into the Automobile Club of France, among the members being James Gordon Bennett and W. K. Vanderbilt. Starting from the suburbs of the city, the crude and noisy machines ran through the Bois de Boulogne, painfully climbed up the

LEVASSOR'S 13-YEAR OLD "RACER" CAN STILL MOVE ALONG.

Suresnes hill and ran towards the southwest. Madame Levassor occupied the spare seat on the racer as far as Versailles, and was naturally at the finishing point, when, after an uninterrupted journey of 48 hours 47 minutes, Levassor came in first on his No. 5. It was about a year after, when running in the Paris-Marseilles and return race, that Levassor met with an accident which was responsible for his sudden death in his workshop seven months later. At the time of his fatal seizure Levassor was engaged in the work of designing a magnetic clutch.

Louis Renault, who entered the game in 1898, shows his first automobile, fitted with a 1 1-2 horsepower motor, constructed when he was nineteen years of age, in a small shop on a portion of his mother's garden. A series of these little cars, with radiator on each side of the bonnet and under it a single cylinder engine, show how improvements were made from year to year. It is of interest to note that the little home factory at Billancourt still stands, now surrounded by the huge modern works. Darracq has a representative in a Léon-Bollée-Darracq car built in 1901 with vis-à-vis body, wire wheels, a single cylinder engine under the front seat and a ponderous flywheel where the running board would be nowadays. Vallée's *Pantoufle*—or Slipper—a curious structure with a slipper-shaped body, is shown as one of the earliest four-cylinder engines. It was built in 1897, and in 1899

MORS RACER ON WHICH GABRIEL WON PARIS-MADRID IN 1903.

it proved that, although it had no changespeed gear, it was capable of completing the tour of France. Modern eliminators of the gear box must certainly look to their laurels. Berliet goes back to 1897 for his first model, with a little two-seated victoria which could boast an inclined steering column, a foot pedal and a side lever. In other respects there is not much in common between the ancestor with its inclined tubular radiator in front, motor hidden under the body, and the present productions of the Lyons and Providence factories. It is interesting to note what a large percentage of the firms building crude cars ten and twelve years ago are in the auto business to-day. There are a few unknown vehicles, but the majority of those on view have direct descendants of no mean order.

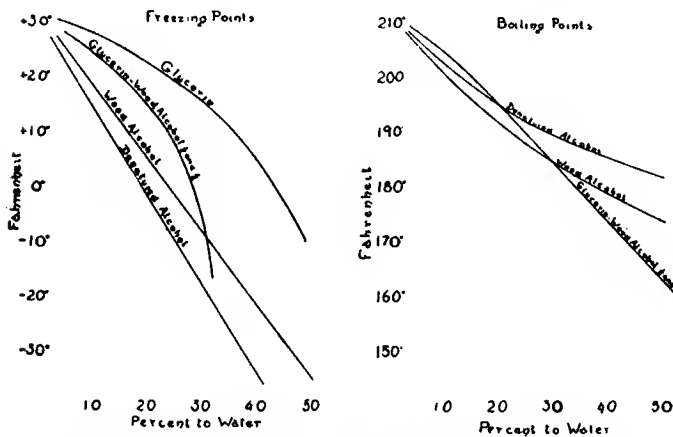

The victors in the long series of cross-country races held from 1895 to 1903 naturally have their place in the retrospective exhibition. Although they were over roads entirely unprotected, speed was so moderate in these early contests that there was really little danger. Year by year the automobiles grew in size and increased in speed until, in 1897, the special train which left the capital at the same time as the first racer, and was announced to arrive at Dieppe before any of the competing cars, landed the batch of officials in thirteenth position. The series of cross-country racers is appropriately closed by the Mors with which Gabriel won the ill-fated Paris-Madrid contest in 1903, at an average speed of sixty miles an hour. Representative of the present era—racing on closed circuits—are two Brasier cars, with one of which They brought the Gordon-Bennett cup home after it had been held successively by England and Germany and retained it for the homeland in the last Gordon-Bennett race.

# DENATURED ALCOHOL TO PREVENT FREEZING

By ROGER B. WHITMAN.

IT is a well-understood axiom that trouble may be avoided by using in the cooling system during the winter months a liquid that will withstand low temperatures, but an axiom that is equally true though not as generally recognized is that the injudicious selection of such a preparation will be a breeder of trouble. It is not difficult to prepare a solution that will remain liquid at temperatures below zero, for the freezing point of water may be lowered by adding to it any liquid of a low-freezing point, or any substance that, while soluble, undergoes no chemical change in the process, and if this were the only consideration winter would present no difficulties to the automobilist, but as the solution should have no deleterious effect on the metals and materials that confine its flow, nor a tendency to clog the passages, the selection of the ingredients becomes more complicated when all these things are considered.

Of the substances offered for the purpose, calcium chloride is the best known in this country, and it is in extensive use for a number of reasons, chief among which is the fact of its low cost and staying qualities. While this salt will undoubtedly

CURVES SHOWING THE FREEZING AND BOILING POINTS OF SOLUTIONS.

serve its purpose so far as low-freezing point is concerned, the hydrochloric acid that it carries will have a corrosive effect on metals if not neutralized, and directions for its preparation always include a warning 'to test for acidity and to neutralize by the addition of an alkali. It should be well understood, however, that a caustic solution will do as much damage as an acid, for aluminum and solder will be attacked and converted into hydrates of aluminum, tin and lead  $Al_2(OH)_3$ ,  $Sn(OH)_2$  and  $Pb(OH)_2$ . Slaked lime or lime water are the usual agents for neutralizing the solution, and if used too liberally the results may be serious.

### Destructive Effects of Calcium Chloride.

That real trouble may result from the use of calcium chloride was shown by the persistent leakage of a centrifugal pump of a car three years old, in which it was found that the aluminum pump housing was entirely eaten through, and the inner surface crusted with a deposit of what analysis showed to be aluminum hydrate. Sodium chloride has been suggested for use as the basis of a non-freezing compound, but it is shown to have disadvantages by the fact that when it is used as a freezing solution in refrigerating machinery it is necessary to line the pump and other iron parts with brass to prevent corrosion.

The most serious effect of the use of a salt in the circulating system is not corrosion by acid or alkali attack, however, but corrosion by electrolysis, which is inevitable if more than one

kind of metal enters into the construction. Other difficulties will arise from the evaporation of the water, for as it is necessary to use strong solutions a slight increase in strength will cause the crystallization of the salts, an action that will tend to clog the pump and radiator passages.

Glycerine and water is a mixture that has been a favorite with the French, and the curve shows that it will withstand fairly low temperatures without congealing. Chemically pure glycerine, as sold for medicinal purposes, has no action on metals, but the glycerine of commerce carries a proportion of the fatty acids that will corrode them and is fatal to rubber. This acidity may be neutralized by the addition of sodium carbonate, but there still remains the most serious drawback, which results from the tendency of an oil to spread over a metal surface and to cling to it. This is strongly manifested in the case of glycerine, and it will form a coating on the surfaces with which it comes in contact, its low specific heat preventing the free radiation of heat as the solution passes through the radiator. Glycerine and water must be kept mixed by the action of the pump, and if the solution is used in the thermo-siphon system the glycerine will separate out with unsatisfactory results.

### Some Characteristics of Wood and Grain Alcohol.

Absolute wood alcohol has a freezing point of  $-151^\circ F.$ , and when mixed with water effects a reduction of the freezing point of the solution. Its present price is 40 cents net in barrel lots, which is not prohibitive, and it is in extensive use. In itself it has no effect on metals, but when heated it tends to liberate formic acid, which is corrosive. Wood alcohol of commerce has a boiling point of about  $150^\circ F.$ , and, as shown by the curve, a solution that will stand  $-20^\circ F.$  will boil at  $180^\circ F.$ , a temperature at which the engine will not have its fullest efficiency, and at which constant replenishment will be necessary. This low boiling point may be raised by using a half-and-half mixture of glycerine and wood alcohol, but the ill effects of the ingredients hardly warrant its use.

With the removal of the tax on denatured alcohol, it becomes possible to use a material that seems to have no bad points and many excellent ones. Grain alcohol has no effect on metals or rubber, and the 2 per cent. or 3 per cent. of wood alcohol that is used as a denaturant is so slight that injury from formic acid may be neglected. Its boiling point is higher and its freezing point lower than wood alcohol, and, as may be seen from the curves, a solution that will stand  $-10^\circ$  will boil at  $192^\circ$ . As it is made under the supervision of the Government, the composition is constant; electrolytic action is impossible, filtering is unnecessary, and its present price of 35 cents per gallon in barrel lots is no bar to its use.

### GASOLINE AND ALCOHOL COST IN FRANCE.

Dealing with the question of industrial alcohol produced mostly from beet root, and for use in the place of petrol for engineering purposes, the *Moniteur Industriel* states that the cost price of gasoline in Paris is now 56 francs the hectoliter (50 cents per gallon), while the cost price of carbureted alcohol is 3.9 francs (78 cents per gallon); but to obtain equal results 5 per cent. more alcohol is required than gasoline. Outside Paris—lower town dues intervening—there is not much to choose between both liquid fuels in regard to total expenditure. In Paris, however, the advantage lies with the use of alcohol, and the "Compagnie des Omnibus" has found that on the 60,000 kilometers (37,500 miles) run by its heavy vehicles, the use of alcohol has resulted in a saving of 300,000 francs (\$60,000). The latter figure appears to us a very high one.

## ADVANTAGES OF THE TWO-CYCLE MOTOR\*

BY HARRY A. KNOX, OF THE ATLAS MOTOR TRUCK CO., SPRINGFIELD, MASS.

THE cycle of a gas engine is the completion of all the actions and functions necessary to obtain one impulse or power-stroke of the piston. If the cycle in an engine is completed in two strokes of the piston, or one revolution of the crankshaft, it is called a two-cycle engine. If it takes four strokes of the piston, or two revolutions of the crankshaft, to complete its cycle, it is called a four-cycle engine. The four actions completing the cycle of the modern gas engine are the suction, the compression, the impulse and the exhaust.

The modern two-cycle engine combines the suction and compression in one stroke. The impulse stroke also performs the initial compression in the crankcase, this compression when transferred into the cylinder at the end of the power-stroke being the means of forcing out the exhaust remaining in the cylinder. All exhaust above atmospheric pressure escapes when the exhaust ports are opened by the piston at the end of the power-stroke. The cycle, involving these four actions, is therefore completed in two strokes of the piston.

There are three kinds of two-cycle engines: First, engines of the Lenoir Type. This engine is now obsolete, as it did not compress its charge before ignition and was therefore very inefficient. This engine sucked a charge into the cylinder for one-half of the piston stroke. At this point the charge was ignited and expanded, giving an impulse to the piston in the last half of this stroke. The return stroke forced out the exhaust.

Another kind of two-cycle engine has in addition to the power cylinder another cylinder, used only for taking in and compressing the mixture. At the end of the power stroke the piston opens the exhaust ports and the compressed charge in the separate compressor is then transferred to the power cylinder through a valve or port in the head of the cylinder. On the return stroke of the piston the charge is compressed, its ignition at or near the end of this stroke giving an impulse to the piston through the next stroke.

The third type of two-cycle engine, and the one most used to-day, especially in automobiles and launches, is the inclosed crankcase type, used because of its extreme simplicity, reliability and compactness. In this type the charge is sucked into the crankcase through a port or valve by the up stroke of the piston. It is partly compressed in the crankcase by the return, or power stroke, of the piston. Near the end of this stroke the piston passes over and opens, first, the exhaust ports, releasing the exhaust above atmospheric pressure, then immediately after opening the inlet or transfer ports. The compressed charge in the crank chamber is then released through these inlet ports into the cylinder, expelling the remaining exhaust. The up stroke of the piston compresses this charge and the ignition occurs near the upper end of this stroke. Seventy-five per cent. of the small American launches are equipped with this type.

Whatever prejudice there is to-day against the two-cycle engine is due largely to the unsatisfactory experience of owners whose boats have been equipped with very crudely designed, cheap and roughly-built two-cycle engines. Most of the early manufacturers of automobiles equipped their cars with four-cycle engines, not because this type had any natural advantages but because it was much better known and had been improved and developed to a greater extent than the two-cycle type. They were at that time interested in the combination that could be manufactured and marketed in the quickest time and with the least effort on their part.

The public to-day has had several years' experience with this type of an automobile engine. They know its advantages and

disadvantages. The result is that they are now demanding an engine that not only runs, but that is of the simplest possible construction, with an abundance of power at all speeds and under all conditions giving silent, smooth running, with an easy quick control of wide range and the least possible friction, adjustment or replacement. The only motor that can possibly fulfill these demands is the two-cycle, and automobile manufacturers in all parts of the world are awakening to the fact.

The following are the difficulties to overcome in applying the two-cycle engine to automobiles:

Difficult to obtain a wide and positive regulation of power and speed, especially at very high and low speeds, without missing impulses. To obtain efficient and economical running under all conditions. To obtain proper lubrication. To prevent crankcase leakage. To obtain a sufficient amount of power with a reasonable weight. The reversing of the motor. The carbonization in the ports. Carbureter troubles. Back firing in the crank case. Difficulty in adjusting bearings.

Automobile manufacturers, knowing the great advantage of a two-cycle engine, have made efforts to use them. They have encountered more or less of these difficulties and after a few ineffectual efforts to overcome them they became discouraged and gave it up. The Elmore company is an exception. They have realized the tremendous advantage of this type of a motor when it had been properly developed and perfected, and have persistently used it for several years on all cars manufactured by them. They deserve great credit for their far-sightedness and perseverance and for the results they are now obtaining.

Some of the numerous advantages of the latest and most improved type of two-cycle engines over all other types, especially for automobile work, are as follows: Its ability with one cylinder to give an impulse to the crankshaft at every revolution, with but three moving or working engine parts, against the thirty or more moving and working parts in a four-cycle two-cylinder engine that are necessary to obtain the same number of impulses. The ability to obtain ample power at all speeds with the least number of parts. The small, noisy, delicate, wearable, adjustable and breakable parts have been eliminated; the large, durable and non-adjustable parts only are the parts retained. The engines are silent, there being no noise except from the exhaust. Due to the simplicity and strength of the working parts great durability and reliability are obtained, with freedom from breakage and replacements.

An important advantage of the two-cycle motor, and that most appreciated by experienced automobile users, is the smooth and even distribution and application of its power at all speeds, due to the great number of impulses.

The two-cycle motor can be made very easy to start as the transfer of the charge from the crankcase into the cylinder is wholly independent of the speed of the motor and is very positive and certain at extremely low speed. This makes it very difficult to stall the engine, and makes it possible, also, when the engine is properly designed, to obtain a slower engine speed than can be obtained from any other type. Again, as the ignition in each cylinder occurs at every revolution, the timing devices can be mounted directly on the engine shaft.

The compression end of the cylinder can be constructed without projections and with the least possible cylinder wall surface exposed to the gases to absorb their heat. This means increased power efficiency, as about 40 per cent. of the heat energy in the fuel is lost through the cylinder walls. Every effort is being made to-day by four-cycle engine builders to reduce this exposed cylinder wall surface. The lack of valves in the head of the two-cylinder motor allows this to be easily accomplished.

\*Paper read before the Springfield (Mass.) Automobile Club.

THE 12-HORSEPOWER EUREKA, WHICH HAILS FROM ST. LOUIS.

### EUREKA HIGH-WHEEL RUNABOUTS FOR 1908.

One of the things that appeared to bid fair to retard the introduction of the buggyabout type of vehicle was the fact that such a number of the machines placed on the market consisted of nothing more or less than stock buggy running gears, on which engines had been mounted. It is hardly to be expected of manufacturers of buggies that they should go into the business of building gasoline engines for this purpose, as there are many makers of experience, with unexcelled facilities, who can do it much better, but merely placing one of these motors on a vehicle originally designed to be drawn by a horse is equivalent to going back to the days of 1892, when it was not possible to do anything else. The builders of the Eureka runabouts have avoided this error, as a glance at the representative of their 1908 line shows. This car has been designed by Charles Zimmerman, and is being turned out by the Eureka Motor Buggy Company, St. Louis, Mo.

The foundation of the chassis consists of a special angle steel frame, which is hot-riveted throughout and effectively braced, while the power plant is carried on a transverse sub-frame located at about the center of the chassis. The motor is of the two-cylinder, horizontal opposed, air-cooled, four-cycle type, so placed that its flywheel represents the center of gravity of the vehicle. The crankshaft carries a planetary gear, from which a single-chain drive is taken to the differential on a countershaft just forward of the rear wheels. Final drive is by means of double side chains. Wheel steer of the rack and pinion type is employed in connection with the standard form of steering knuckles, this representing quite an exception to the practice followed where this essential is concerned on the average buggy type of machine, some of them being of an extremely crude nature. The motor develops 12 horsepower at 1,400 r.p.m., giving the car a speed up to thirty miles an hour on the high gear. The wheelbase is 70 inches and the wheels are 36 inches front and 40 inches rear.

### INFLUENCE OF EXTREME COLD ON RUBBER.

Although it has been known in a general way that under extremes of cold rubber lost most of its valuable qualities, little scientific data has been sought for by automobilists, for the simple reason that cars have been rarely operated under extreme conditions of temperature. With the proposed automobile tour from New York to Paris, interest has been drawn to this subject, with a view to obtaining a serviceable tire for use in the extreme cold of Alaska and Siberia.

At the factory of the Liquid Carbonic Company in New York, David Hays, manager of the Healy Leather Tire Company, has made a series of tests with strips of vulcanized rubber with a view to obtaining data of their performance under extremes of cold. In an artificial temperature which could be reduced to

108 degrees below zero, thin strips of vulcanized rubber taken from the treads of various well-known makes of pneumatic tires, were cut up, doubled over and held in a little clip in such a way that they could be released at pleasure. When the temperature in the testing chamber dropped to 30 and 40 degrees below zero, the action of the rubber was quite sluggish, the pieces assuming their original shape very slowly on the release of the spring. When the rubber was subjected to a temperature between 40 and 50 degrees below zero, it was found to harden in the position in which it was held by the clip and did not unbend on the application of heat until after a certain interval.

It was found that the purer the rubber the better was its ability to withstand cold. For a pneumatic tire, however, it is impossible to use pure Para rubber without compounding it with other materials, as in its pure condition it is too tender to give service on the road. Leather, as sometimes used for automobile tires, was put to the same tests without any apparent loss of elasticity.

### INCREASING THE HEADLIGHT'S EFFICIENCY.

It would hardly appear possible at first sight that merely a slight change of position could have much effect on the efficiency of an automobile's headlight, though it must be evident that there must be some one position in which the lights will illuminate the road ahead in the most effective manner from the driver's point of view. Various experiments in lamp placing have been tried by various automobile builders, but the problem appears to have finally resolved itself by the adoption of the frame location, which is now practically universal.

The makers of the Northern cars have never been quite satisfied with this custom, and have made the radical change shown by the accompanying photograph, from which it will be seen that the headlights are carried on special supports fastened to the fenders. Regarding this change, V. M. Gunderson, general manager of the Northern Motor Car Company, says: "We think we have the best of reasons for placing the lamps as shown on all of our 1908 models. We did not make the change without very careful experimenting, and we found that this position increases the road-lighting efficiency of the searchlights nearly 100 per cent. We have overcome the objectionable feature of excessive vibration by bracing the under side of the fender.

FRONT VIEW OF NORTHERN, SHOWING ARRANGEMENT OF LIGHTS.

**STANDARD AIR-COOLED BUGGYABOUT CHASSIS.**

For the coming season the Neustadt Automobile and Supply Company, St. Louis, Mo., will make a specialty of complete buggyabout chassis. While both are to be equipped with air-cooled motors of the horizontal twin-cylinder opposed type, one will have the power plant placed longitudinally under the body and will be equipped with a regulation planetary change-speed gear and single chain final drive, while the other, which is illus-

PLAN VIEW OF NEUSTADT AIR-COOLED, FRICTION-DRIVEN CHASSIS.

trated by the accompanying cut, will have the motor placed transversely forward at the end of the frame, and will be equipped with a friction type of transmission. Steel and aluminum are the materials used for the wearing faces of this change-speed gear, steel plates being employed for one surface and a special aluminum coating, which is said to be superior to the usual aluminum sheets employed, being utilized on the other. Control is by pedal, the moving member sliding on a feathered shaft by means of fingers connected with bell cranks, to give the variable forward speeds and reverse. Final drive is by double side chains from sprockets on the ends of the countershaft, as

THE NEUSTADT FRICTION DRIVE SHOWING ECCENTRIC TAKE-UPS.

shown in the second illustration depicting the friction transmission itself. The chief feature of the latter, however, is the use of eccentric take-ups to provide the necessary pressure between the friction surfaces. These eccentrics are placed on the countershaft and are combined with its supporting bearings. The device is thus extremely simply and durable, at the same time insuring a positive and equalized contact between the two faces with a minimum pressure. This car and its transmission are also made with single-chain drive. Steel-clad bodies can be supplied to fit.

**HORIZONTAL MOTORS WITH NEW FEATURES.**

Practice has been standardized to such an extent where the building of that typically American style of gasoline motor, the two-cylinder horizontal opposed type, is concerned that it would be difficult for the average autoist to distinguish a great many of the makes that are now on the market without close inspection. And one of the chief things in which many of these motors could be vastly improved is the matter of accessibility. In designing their line the makers of the Westerfield motors, the Westerfield Motor Company, Anderson, Ind., have borne this

VIEW OF WESTERFIELD MOTOR WITH COVER PLATE REMOVED.

in mind, so that it is quite safe to say there are few horizontal twin-cylinder motors that can surpass them in this respect. But accessibility means considerably more than what has been aptly termed "getatability," for this advantage is of doubtful value if, in the process of getting at a part, the adjustment of two or three others must be disturbed.

But that the Westerfield motor has been made the subject of close study on this score, and all these points have been taken into consideration, will be evident from a study of the accompanying cuts of it. The first, showing a plan view of the motor, with the upper half of the crankcase removed, reveals the fact that it is made with a semi-spherical gray iron crankcase.

WESTERFIELD CAMSHAFT SUPPORT.

On removing this, the entire cam mechanism becomes accessible, and in order to render the crankshaft and its bearings equally so the camshaft and push rods are all mounted on a circular carrier, which is shown separately in the second photograph. It will be evident that the removal of this essential does not disturb any of the adjustments of its parts. The crankcase cover proper is held down by the four wing nuts shown. The oiling system is also especially meritorious, as it is entirely self-contained, being driven by a spiral gear on the timing shaft inside the crankcase.

MOUNTAIN CLIMBING BY AUTOMOBILE, AT THE SUMMIT OF MONT PRARIOR, ON THE FLANK OF MONT BLANC, GRADES 30 TO 40 PER CENT.

### NEW BOOKS FOR AUTOMOBILISTS.

**A Book of Interest to Foreign Tourists.**—In "Castles and Chateaux of Old Navarre and the Basque Provinces" Francis Miltoun has produced another work quite up to the standard of his already well-known books on tours and touring in France. There is nothing of the stereotyped guide book about this work, nor is it an account of an automobile tour, yet it is likely to appeal more strongly to automobilists than to any other class, for the simple reason that those who like to explore the romantic and picturesque corners of the globe almost exclusively employ the most modern means of locomotion. There is no lack of romance, picturesque local color and historic recollections in the line of Pyrenean provinces lying along the Spanish frontier from the Gulf of Gascony to the Mediterranean, and Francis Miltoun knows how to paint it in a way that will appeal to those who have toured in this land of sunshine and enchantment, and excite the curiosity of those who have not yet pushed so far afield. The book is not intended to serve as a guide to the Pyrenees, but its perusal either before or during a tour in this district cannot fail to be instructive and interesting to tourists. "Castles and Chateaux of Old Navarre" is handsomely illustrated by Blanche McManus and published by Page & Company of Boston.

**Italian Road Maps.**—Four more sections of the complete road map of Italy, the publication of which will occupy five years, have been issued from the headquarters of the Touring Club of Italy, at Via Monte Napoleone, Milan. With the present issue, which carries the number of sections covered to ten, the Touring Club of Italy will have distributed 800,000 maps to its 65,000 members. The peninsula has been divided into fifty-eight sections, a map of each being published on a large scale in eight colors. The work is one of the most important ever undertaken in the interests of Italian touring, and is particularly valuable in view of the increase in touring in Italy.

**Italian Automobile Textbooks.**—Students of Italian will find something to interest them in two publications from the publishing offices of Ulrico Hoepli, of Milan. "L'Automobilista," by Dr. Pedretti, deals with automobile construction in a thorough manner, and is not merely confined to land vehicles, but has something to say on motor boats and submarines, American craft not being overlooked. "Guida del Meccanico Chauffeur," by the same author, is a guide for the mechanic and driver and concerns itself chiefly with ignition, carburetion and the general care of the automobile. Both works are freely illustrated and issued in convenient size.

### ENGLAND, BELGIUM, ITALY TO RACE.

LONDON, Dec. 14.—After a long period of challenges and counter-challenges, statements and counter-statements, in which S. F. Edge and the Darracq representatives have not played the least important part, the Brooklands Automobile Racing Club has decided that races between challengers could only be decided on the Weybridge track when all preliminary proceedings had been conducted through the club. Thus with one blow press agents have been silenced and columns of wearisome correspondence have been cut out of the newspapers. Edge has now made four official challenges through the club, and three of these have been accepted. The Metallurgique Company of Belgium has taken up challenge No. 1, which is to race a four or six-cylinder Napier car against any automobile propelled by an internal combustion engine whose cylinder dimensions do not exceed 64 under the D2N formula, equivalent to 26 horsepower under R. A. C. rating, weight 2,000 pounds, distance five laps from standing start. O. Cupper will be the driver. The same firm and same driver have accepted the Napier challenge for 40-horsepower cars of 2,500 pounds minimum weight, for a distance of six laps, with standing start. Certainly the most interesting race will be the one between a Napier, with a driver yet to be appointed, and Nazzaro on a Fiat, for a distance of ten laps, standing start, maximum cylinder dimensions to be 225.1 and minimum weight 3,000 pounds. On the R. A. C. formula this gives 90 horsepower. One of the challenges, for cars rating at 60 horsepower, has not yet been accepted. Stakes of \$1,250 a side have been deposited by each party with the club officials. All the matches must be decided on a date to be chosen by the Brooklands Club between May 14 and July 1. It is expected that the Darracq agent here will enter the lists for speed supremacy and add to the interest of these important tests for commercial and national honors.

### NEW ELECTRIC TIMER FOR BROOKLANDS.

LONDON, Dec. 14.—Brooklands track has just been equipped with a new electric timing apparatus invented by Colonel H. C. L. Holden and K. Elphinstone. It is entirely automatic in operation, the instrument consisting in brief of a traveling band of paper moving at a fixed rate of speed, seconds and fractions being recorded on its surface by three electrically actuated pens. The passage of a car over the finishing wire is recorded on the margin of the same strip by an electro-magnetic device. Duplicate records are made and notes can be written on the band while it is in motion.

Only a Temporary Setback for 1908 Selling Season.

In the failures that have come during the last half of the present year many have been unable to see anything but calamity ahead for the automobile industry. They have been unable to realize that in two of the crashes that have taken place the concerns have not gone down to ruin. The temporary financial stringency has merely been responsible, in their case, of letting the water escape; has only precipitated what would have inevitably occurred sooner or later. Several other firms of standing have been legitimately embarrassed at the same time, but it is safe to say that not one of them will be forced to the wall for good and that with the resumption of normal conditions nothing further will be heard of their difficulties. There are still others who have gone down during the same period, but they belong to that numerous class that would have succumbed to the stress of circumstances regardless of the existence of abnormal conditions. Ignorance and lack of capital are as much a drawback in automobile building as in any other line, so that such failures have no bearing one way or the other.

Where the selling end of the automobile industry is concerned—its very life, so to speak—it would be difficult to be other than optimistic without totally disregarding the facts. According to those same calamity howlers who can see nothing but a vast pall over the entire industry, there are no cars being sold, none have been sold since October last, and few will be sold during the coming year. As a matter of fact, one New

York dealer alone took orders for three cars at between \$4,000 and \$5,000 each, receiving the usual cash deposits thereon, during what was generally conceded to be the week of the greatest depression. The business done at the Chicago show was very encouraging and the reports of dealers in various parts of the country are equally so. That people generally regard the present state of affairs as but temporary could hardly be better evidenced than by the fact that during the week just past one Newark, N. J., dealer took orders for no less than seven cars for spring delivery.

If some of the people who are steeped so deeply in prospective misery and hard times that the sun scarcely shines for them any longer would take the trouble to ascertain the true condition of affairs, it might relieve them of a world of worry. Six months from now the industry in general will be congratulating itself on the events of the past eight or ten weeks, and only regretting that the knife did not go deeper, thus permanently eliminating more of the undesirable element.

Taxicab as the Forerunner of the Commercial Era.

It is not difficult to understand why the commercial vehicle, with its great advantages, has not made greater headway up to the present, when all the circumstances are taken into consideration. The same reasons that combined to delay the introduction of electric power in the railway world has had its influence here. Huge sums invested in horses and trucks could not be sacrificed for something that has yet to prove its overwhelming superiority, where the business man is concerned, for the same man who lavishly opens his pocketbook for the maintenance of his own car figures ton miles to a cent when it comes to delivering goods. This has made commercial vehicles difficult to market, so that the builder of automobiles has naturally worked along the line of least resistance in continuing to devote himself to the pleasure car.

But during the past year a new factor has come on the scene. This is the taxicab, and it is bound to make its influence felt in the near future. Some expert prophesiers can already see the time, two or three years ahead, when the taxicab shall have become such a wreck that unless New York's already high cab fares are raised the promoters will be unable to run the vehicles at a profit. It is all very well to count your profits now, when the vehicles are new, say these knowing ones, but wait—just wait till they grow old and the green driver and New York's pavements have got in their fine work.

Depreciation naturally increases with age, but the longer gasoline cabs are run the more successfully will they be operated, and they will furnish a striking example of what can be done. In fact, it hardly seems too much to say that the taxicab will be responsible for facilitating the coming of the commercial vehicle in large measure.

What Does It Cost to Run an Automobile?

It would appear as if this simple query were susceptible of about as many shades of answer as the famous one regarding matrimonial ventures. It costs one autoist several hundred dollars for tires alone in the course of a year, while another finds that he spent but a fraction of that amount to cover almost the same distance under very similar circumstances. One man's repair bills are excessive, while another gets an equal mileage and more enjoyment out of his at a cost but slightly in excess of what he would have had to pay to keep a horse in oats and shoes during the same time, and the queer thing about it all is that frequently the various cars have been maintained under rather similar conditions. The carefully itemized account of the Californian who spent almost half the first cost of the car in maintaining it the first year finds its antithesis in that of the autoist who ran his car for two years for little more than \$100

## A.A.A. PUTS STOCK CAR MEET AT SAVANNAH UP TO MAKERS

IF the automobile manufacturers consider a stock car meet well worth while at Savannah, Ga., one will be held during the third week in March. But President William H. Hotchkiss, of the American Automobile Association only wants the meet held if the manufacturers so desire, and they have been asked to express their opinion in a letter which the president of the national organization has had sent out by Secretary Elliott. The suggested course would appear to be an ideal one. The officials and inhabitants of Savannah are unanimous in seeking a series of contests, and the course will be guarded by militia and oiled for its entire length. There is no place in the country at the present time where conditions can be found as favorable as those presented by the picturesque Georgian city, which is easy of access, both from the North and from all points in the South. Following on the heels of the Florida meet, the Georgia affair should add to the general interest in automobiling, particularly because it will provide for just such cars as are supplied to the automobile-buying public.

There will be a meeting of the executive committee of the A. A. A. Racing Board on Saturday morning next, at 437 Fifth avenue, to be followed in the afternoon by a session of the executive committee of the A. A. A. Board of Directors. At those two meetings a decision will be reached regarding the Savannah meet, the action to be based upon a consensus of opinion of the American manufacturers, to all of whom has been sent the following letter:

Gentlemen:

New York, Dec. 23, 1907.

Pursuant to the community of interest plans outlined at conferences held recently at Chicago between representatives of the N. A. A. M., the A. L. A. M., and the A. M. C. M. A., and this association, permit me to lay before you the following concerning a three-day tournament for stock cars at Savannah, Ga., during the week of March 15, 1908.

A committee consisting of F. G. Webb, representing the Racing Board; N. H. Van Sicken, representing the Technical Board; and the undersigned visited Savannah recently upon the invitation of the Savannah Automobile Club, carefully inspected the proposed course, conferred with the civil and military authorities, investigated hotel and transportation facilities, and has recommended favorable action by the association. We are, however, unwilling to take such action, unless some or all of the contests suggested are desired by a sufficient number of American manufacturers.

The report of the investigation committee may be summarized as follows:

Course: Practically twenty miles, or for short races or where a small number of entries will permit, a course of ten miles, the latter with long banked turns, and thus practically a race track such as does not elsewhere exist in the world. On both courses two straight stretches practically level, four miles each. On the

larger course, some sharp turns, which will be eliminated, if desired, and some considerable grades. Twelve turns capable of reconstruction and banking, so that at least ten can be taken at speed. Road surface hard, and, save in one or two places for short distances, broad; equal in every way to that of the last Vanderbilt Cup course. Practically no intersecting roadways.

Policing: By State troops, from 1,200 to 1,500 being promised by the military authorities. Roadways joining the course fenced during progress of races. Entire course oiled.

Transportation. By steamers, three each week to Savannah from New York, and two each week from Boston, Baltimore, and Philadelphia, with low round-trip rates and average freight for cars, \$25; also by railroad, nine trains daily from New York on different roads, and corresponding facilities from other centers.

Hotels: Facilities ample, three large hotels, all of them within a few miles from the course.

Co-operation by local authorities assured; the committee in charge, including the Mayor; the presidents of the Chamber of Commerce, Board of Trade and the Cotton Exchange, highway officials, militia commanders, etc.

Time: The second week after the Ormond-Daytona carnival. At this time Spring is far along in Savannah; the return of the Southern tourists has begun; fine weather and a large attendance, not only of strangers, but of residents of Savannah, Atlanta, Charleston, Birmingham, and the leading Southern cities, is certain.

In view of this report, the rules committee of the Technical Board met at Buffalo on December 21, and adopted tentative rules for suggestion to the Racing Board. These provide for a series of contests between strictly stock cars with racing bodies, for say light cars, heavy four-cylinder cars, high-powered runabouts, and six-cylinder cars. Handsome trophies will be offered for each event, that for four-cylinder cars of the larger type a challenge cup given by the City of Savannah. Entrance fee will not exceed \$500. All races would be from 150 to 300 miles.

Conferences with manufacturers during the past few days indicate a desire for contests of this character in the early Spring, under the auspices of the A. A. A. It is suggested that present financial conditions make important the publicity of a national event of this character before the end of March. The Savannah plan seems to afford the only opportunity where weather and road conditions are practically certain, and where alone in the United States proper policing of the course can be had at the present time.

That we may have the advantage of your views, (1) as to whether such a stock car tournament is desirable, (2) if so, as to what races should be held, and (3) generally, you are earnestly requested to write or wire the undersigned at once. Owing to the shortness of the time, a decision must be reached at meetings which will be held here Saturday, December 28. Therefore, kindly favor us by forwarding a prompt reply.

The races, if held, will be under the auspices of this association, and personally managed and supervised, the events themselves by the Racing Board, which conducted the last Vanderbilt Cup contest, assisted as to all technical matters by the Technical Board.

F. H. ELLIOTT, Secretary, A. A. A.

By order of PRESIDENT WILLIAM H. HOTCHKISS.

## REEVES AND MARMON RETURN FROM EUROPEAN PILGRIMAGE

ALFRED REEVES, general manager of the American Motor Car Manufacturers' Association, and Howard C. Marmon, a prominent member of its technical committee, on Saturday last returned from their visit to the European shows, having come home on the southern route, via Italy and Mediterranean ports. The *Kaiserin Augusta Victoria* had a delightful homeward voyage, experiencing only one rough day.

Interviewed upon the foreign situation, the comments of Mr. Reeves included the following:

"One of the most interesting things, to my mind, was the great progress that has been made in commercial vehicles. The last five years has made wonderful changes in the traffic conditions abroad, and I could hardly believe that it were possible in that short time to supplant so many horse-drawn vehicles with motor-driven machines. Particularly in London and Paris, the motor cab is crowding the horse-drawn rig. In Paris, the latter has had to have a taximeter equipped, so that now the proverbial overcharge of the Parisian hackman is only history. There are hundreds of motor

'buses, most of them double-deckers, although future ones will have one deck only, so as to handle easier. The terrific test to which motor cabs and 'buses are subjected has revised ideas as regards clutches, gears and brakes. There are about 3,000 motor taxicabs in Paris and 800 in London. Almost every vehicle in Paris, even the horse-drawn cabs and coaches, have pneumatic tires. The solid tire, except on 'buses or trucks, is a rarity. Power trucks of steam and gasoline are used for hauling coal and for all kinds of work, ranging from the carrying of sixty passengers or five tons of coal to delivering hats and shoes; and this in spite of gasoline selling at about 40 cents a gallon.

"Among the pleasure vehicles, the tendency is toward the light four-passenger touring car of 24 horsepower or less. Most of the concerns that build big cars are also building small ones. Some of the small ones have only one cylinder, but none of them sell within the price of our small cars. It is my judgment that we have a good future in the foreign markets with the small types of cars which we manufacture in such large quantities, but the foreign markets will have to be entered and handled in a way entirely different from the methods followed here."

## NO GERMAN NATIONAL SHOW IN 1908; NEXT ONE 1909

BERLIN, Dec. 15.—There will be no Berlin show next year, as the German Society of Motor Car Dealers and Makers, without even entering into the matter of Berlin or Frankfort as a possible site for the 1908 show, resolved with only three dissenting votes to hold no exhibition again until 1909. All members of the Society had to agree to participate in no show whatsoever until September, 1909, otherwise a fine of 100,000 marks would become payable.

America had two representatives present—Ford and Pope-Toledo—when His Royal Highness Prince Henry of Prussia opened with royal pomp Berlin's eighth automobile show, held in the hall of the Zoological Gardens. As is usually the case, the ceremony was a purely social one, attended by about one thousand guests of the Imperial Automobile Club, elegant, well-dressed men and women and brilliant uniforms harmonizing well with the handsome decorations and massed foliage. The Duke of Ratibor welcomed the Prince, who was delegated in the enforced absence of the German Emperor, and pointed out that Germany's industry had now reached a point where it need fear no foreign competition. In a short speech Prince Henry declared the show open, called for three cheers for the Emperor and finished the ceremony by an official tour of the exhibition.

This year's show, the second in the present home, excels all predecessors, but is considerably hampered for lack of space. There is a movement in favor of removing to Frankfort, where a huge exhibition hall is now being erected. A plain but pure style of decoration has been adopted for the Zoological Garden show, contrasting advantageously with that of other years.

Mercedes, Benz, Adler, Opel, N. A. G. and Eisenach, as most important of the home firms, occupy the main portions of the central hall. Other German firms occupying important floor space are North German Electric, Argus, Deutz Gas Motor Company, Victoria, Siemens-Schuckert, Turicum, Quest, Remickendorf, Bergmann, Laurin & Klement, Stoewer, Horch, Duerkopp, and Loeb. France, Italy, Belgium and America form the foreign contingent, the principal importers being Ford, Pope-Toledo, Berliet, Renault, Fabrique Nationale, Protos, Itala, Bianchi, Clement-Dialto, Martini, Pipe, Minerva, Metallurgique, Isotta-Fraschini, Fiat, De Dion, Coventry, Panhard, Daimler, Dunlop, Michelin, and Continental.

### What Prince Henry Said at the Banquet.

A banquet took place at night in the Kaiserhof Hotel, 400 guests being present, with Prince Henry of Prussia in the seat of honor. There were at the banquet the Home Minister, Minister of Railways, Chief of the General Staff, the Police President and a crowd of persons of standing in the official and motoring world. Referring to the cup presented by him, the prince said:

"I have promoted this tour because I knew that the Herkomer event drops into abeyance and because our extremely active industry was once more eager to show what it could do. It would not have been possible for me to arrange such a competition had

not the Government shown a very friendly attitude towards me, and it is my pleasant duty to render our thanks for this. Furthermore, gentlemen, a Damocles sword in the shape of the automobile liability law has hung over motorists; I am in the happy position of being able to state that we may look towards this law in peace and quiet."

Prince Henry thereupon proposed the Imperial toast, which was responded to with much vigor.

### Prince Henry Tour Only Big Similar Event.

Germany's sole big touring event next season, for the cup presented by Prince Henry of Prussia, will take place from June 9 to 17 and will be open to all drivers. The donor originally intended the event to be an amateur one, but as the industry is otherwise given no chance next year, owing to the indifferent attitude of the officials, this intention has been withdrawn. The tour starts in Berlin, with Dantzig as goal for the first day, Stettin for the second, and Kiel for the third. The fourth day will also be spent at Kiel, and the journey continued on the fifth day to Hamburg; speed trials will be held en route. From Hamburg the road leads southwards to Dusseldorf, and the finish is at Frankfort. Prussia alone will be the site of the event, as the itinerary shows. The Imperial A. C. promotes the tour, and Count von Sierstorpf, Baron Brandenstein, Count Arco and Dr. Levin-Stoelting are on the working executive. Further prizes have been promised by Princess Henry of Prussia, the Grand Duke of Hesse, and the cities of Hamburg and Frankfort.

### Some German General Gossip.

France, Spain and America are three of the countries which have challenged Germany for the aerial Gordon-Bennett Cup next year; France will send a full team of three balloons. Frank Lahm is in Berlin at present to study the German military balloon system; on his return to America he intends embodying the results of his studies in a dirigible balloon, to be constructed conjointly with Captain Chandler. The balloon is to be put to a first test early next spring at Fort Meigs.

The German Home Office is promoting an inquiry by means of which it hopes to arrive at a clear insight into the output and condition of the German automobile industry. The authorities have been assisted in this by the Imperial Automobile Club and the leading firms themselves.

Baron von Brandenstein, formerly the general secretary of the Imperial Automobile Club, and ever since his connection with it a member of all the highest committees and honors, has been compelled to withdraw from all such posts owing to lack of time. The official withdrawal will take place after the close of the Berlin show, for which he is largely responsible. The name of Brandenstein and that of the Imperial Automobile Club are synonymous and German automobilism owes the Baron a huge debt of gratitude.

## MANAGER MILES PREDICTS NO AMERICAN SHOW UNTIL 1909

CHICAGO, Dec. 23.—According to Samuel A. Miles, general manager of the National Association of Automobile Manufacturers, and also manager of the annual show of the association in Chicago, there will be no show during 1908. Manager Miles has never been in favor of an early show, and as there seems to be little doubt that the prominent men in the industry are not satisfied with the plan introduced this year the consensus of opinion in automobile circles is that it will be February or March, 1909, before the next shows are held under the N. A. A. M. auspices.

"The dealers seemed at many disadvantages in having the show as early as it was held this year," says Mr. Miles, "and there is little doubt in my mind but that 1908 will go by without a show, either in New York or Chicago. The next N. A. A. M. show probably will be held in February or March, 1909."

Mr. Miles suffered an innings of illness after the Chicago show, probably owing to the hard work and the inclement weather, but is now out again and intends to be in New York City about the first of the new year.

## HOLIDAY HAPPENINGS OF THE AUTO CLUBS

### QUAKER CITY CLUB'S BIG ENDURANCE RUN.

PHILADELPHIA, Dec. 23.—At the rate at which entries are pouring in upon Chairman Johnson, of the Quaker City Motor Club's contest committee, the Philadelphia-Allentown-Philadelphia endurance run, to be held January 1 and 2, under the auspices of that organization, will far exceed in importance not only last year's affair, but any similar contest held in the East last season, barring, of course, the annual A. A. A. fixture.

The committee having decided upon four classes—touring cars, roadsters, runabouts and a "purely-for-pleasure" contingent, including all three—many local agents and branch managers have entered at least one car in each class. For instance, there will be four Pullmans, three Fords, four Maxwells, three Frayer-Millers, two Studebakers, and the same number of Autocars and Loziers, several Packards, at least three Stoddard Dayton, and so on—all these from tradesmen.

What is proving decidedly attractive to the latter class of entrants is the inclusion in the run of the pleasure aggregation.

### CONCERNING THAT NEW JERSEY LAW.

NEWARK, N. J., Dec. 23.—The New Jersey Automobile and Motor Club held an open meeting on Thursday night last, to which were invited representatives of the various clubs in the Associated Automobile Clubs of New Jersey. The response to the call was not as general as it should have been, for outside of the members of the big Newark club, only the Mercer County Automobile Club and the North Jersey Automobile Club sent representatives, Wilber F. Sadler, president of the State body, being the Trentonian present, and G. A. Post, speaking for the Patersonians.

There was a general discussion of the law after President Sinclair had surrendered the chair to Chairman Crosby, of the local club's legislative committee. J. H. Wood offered various amendments, acceptable to those present, looking forward to the improvement of the present Frelinghuysen law, one of the amendments offered giving non-residents ten days' recognition of their home licenses. It was decided to have each

IN THE VICINITY OF READING, PA., THE QUAKER CITY MOTOR CLUB PATHFINDERS FOUND SOME REAL WINTER.

who may patter along at their own sweet will, regardless of controls—aside from the necessity of finishing within the time limit set by the committee. There will be an incentive even in this class, for a loving cup has been hung up for the "most popular" driver—and the award will be made to him who receives the greatest number of votes, the privilege of dropping a ballot being confined to contestants. The large number of participants who would have remained out but for this innovation are hearing reports from up Allentown way which will insure their presence even if the weather clerk should prove fickle. The automobilists in the Lehigh county metropolis are planning a great reception for the tourists, rumors of turkey suppers, theater parties, and dances have filtered through until the "nothing-but-pleasure" bunch are fairly aching to start.

Ten days ago Chairman Johnson and a score of fellow-committeemen and clubmates took a "pathfinding" trip over the course for the purpose of establishing checking stations and arranging for accommodations at the control at Allentown.

The course is an unequal sided triangle, with Philadelphia, Easton and Reading at the three angles. The country to be traveled over is beautiful, even in winter, and for a great part of the distance the route follows the windings of the Delaware, Lehigh and Schuylkill rivers. On the second day the route leads over the watershed between the Delaware and Schuylkill, and the entire route will present difficulties sufficient to eliminate any but the best cars in first-class condition.

club in the State body designate a member of a general committee, which will then be called together by President Sadler. It is possible that this committee may have a special conference with Senator Frelinghuysen, who is said to be agreeable to changes in the present drastic law, which bears his name.

### CLUB MEMBER RESIGNS IN FACE OF CHARGES.

BALTIMORE, Dec. 23.—Rather than stand trial before the board of governors of the Automobile Club of Maryland on the charge of reckless speeding within the city limits, Frank Brown, Jr., son of ex-Governor Frank Brown, the Democratic city organization leader, resigned as a member of the club. Under the by-laws of the club such a resignation makes it impossible to take action resulting in the expulsion of a member. The directors of the club, however, passed resolutions expressing their "abhorrence" of Brown's conduct in the action which resulted in the death of James Grinnell.

The board of directors further decided to prefer charges against two other members, Edward L. Bartlett and Howard A. Gill, for violations of the speed limit. The violations charged against these two members occurred October 1, when, it is stated, they participated in a race through the streets.

Osborne I. Yellott, counsel for the Automobile Club of Maryland, has drafted a bill designed to elevate automobiling in this section and lessen the prejudice against the sport. The

bill provides for the appointment of a commission by the Governor, who shall have the right to license cars, examine drivers to determine their qualification and fitness to operate the machines, whether owners or professional chauffeurs; investigate violations of speed laws and accidents resulting from reckless driving and to have absolute power as to the suspension and revocation of licenses. The speed limit proposed has been successful in Massachusetts and Connecticut and is proposed to be adopted in the uniform State law recommended by the American Automobile Association.

In speaking of this portion of the bill, Mr. Yellott said:

"The effect of such a provision is to vest in the magistrate or court some discretion relieving the motorists of constant fear of arrest if they slightly exceed the speed limit on an open highway where there is no one near whose safety will be endangered, but making him realize that he must not exceed the limit in cases where there are other people on the road."

#### WORCESTER'S CLUB TO GO AFTER UNATTACHED.

WORCESTER, MASS., Dec. 23.—The Worcester Automobile Club is going to commence active missionary work among the motorists of Worcester county and Central Massachusetts to enlist them in the line up of the Massachusetts State Automobile Association in looking after the interests of all the motorists of the State in the session of the legislature in January. The names of registered cars in the center of the State, the portion which comes in the jurisdiction of the club, shows there are over 1,000 owners' names on the list. There are many of them in the ranks of the club, but there are others who have not lined up with the rest of the motorists, and the club is after these and is going to bring them into the fold.

The State association will continue the coming legislative session the work which has been done in past sessions, and this will take money, and the more men there are in the organization the more influence the movement by the motorists will have. The light bill, calling for lights on all vehicles using the public highways at night, is one of the measures which the motorists want to see passed at the State house this winter.

#### F. B. HOWER NOW LEADS THE BUFFALO CLUB.

BUFFALO, Dec. 23.—New officers are at the helm of the Automobile Club of Buffalo. The annual election was held on Monday night of last week and the following were selected without opposition to serve for the ensuing year: President, Frank B. Hower; vice-president, John M. Satterfield; treasurer, Laurens Enos; secretary, Dai H. Lewis; directors, E. R. Thomas, E. H. Butler, Charles Clifton, James N. Byers and George C. Diehl. More than 270 votes were cast.

Seymour P. White, retiring president, made a short address in which he thanked the members for cooperating with him in his work last year. When he had finished Mr. Butler presented to him a loving cup on behalf of the club. William H. Hotchkiss, president of the American Automobile Association, was also one of the speakers.

A splendid entertainment pleased the large attendance. The program was varied enough to please everybody. After the election and during the entertainment refreshments were served.

#### MILWAUKEE CLUB'S UNIQUE ROAD CAMPAIGN.

MILWAUKEE, Dec. 23.—Believing that the most efficient way to bring about the greatest road improvement in the shortest time is to interest the farmer, Emil Schandain, vice-president of the Milwaukee Automobile Club, has proposed a unique plan, involving the cooperation of the farmers of Wisconsin in the good roads movement. The club will immediately undertake the raising of a suitable fund, though the residents of the districts affected by the improvements will not be asked to contribute. People who have summer homes along some of

the beautiful Wisconsin drives will be expected to subscribe liberally, however. With the funds thus raised, a road building contest is to be set afoot between the various districts in question. The grand prize is to be \$1,000, with numerous others ranging down to \$250, and further sums from this down to \$25, as a cash premium, all to be awarded for the greatest improvements to be made within a certain time.

The first experiment, already planned, will be carried out between Milwaukee and Oconomowoc, the contest beginning in the early spring. W. O. Hotchkiss, superintendent of the economic and good roads division of the geological survey, is said to be favorably inclined toward the plan, and the State Good Roads Commission will also be asked to cooperate. Under the plan, as adopted by the automobile club, the farmers will be asked to inspect the roads in each other's districts, and the club will furnish cars to carry the agriculturists around for the purpose.

#### NEWBURGH CLUB ACTIVE FOR NEEDED REFORMS.

NEWBURGH, N. Y., Dec. 23.—At the last meeting of the Automobile Club of Newburgh it was decided to take active steps to induce the local authorities to have signboards erected in the vicinity of this city, as prescribed by Section 5 of the State Highway Law. The club went on record in favor of a uniform automobile law governing automobiles in New York, Massachusetts, Ohio, Illinois, New Jersey and Pennsylvania. A motion was adopted requesting Congressman Bradley to use his influence to secure the passage of certain bills which are now pending in Congress to provide for registration which will enable automobiles to be operated in various States under one license. The club also endorsed several proposed amendments to the statutes affecting automobiles which are to be introduced at the coming session of the legislature. The meeting was well attended and comprehensive by-laws reported by the committee were adopted.

#### CHICAGO AUTOMOBILE CLUB PICKS CHAIRMEN.

CHICAGO, Dec. 23.—According to President Ira M. Cobe, the Chicago Automobile Club intends to challenge in a friendly rivalry the energetic Chicago Motor Club, which has conducted several very successful contests during the past year. The older club is planning a program of technical contests, with one in view which he states will be novel and create a good deal of discussion. With the exception of the Technical Committee, the chairmanship of which was declined by F. E. Edwards, a member of the Motor Club's similar committee, these selections of chairmen are expected to be accepted: Runs and Tours, A. J. Banta; Racing, C. E. Gregory; House, Claude Seymour; Membership, T. J. Hyman; Auditing, D. A. Moulton; Good Roads, F. B. Gethro; Legislation, Laws and Ordinances, Sidney S. Gorham; Entertainment, J. T. Leimert; Art, F. H. Pietsch.

#### L. I. A. C. STANDING COMMITTEES FOR 1908.

BROOKLYN, N. Y., Dec. 23.—Acting in accordance with the constitution and by-laws, President Charles Jerome Edwards, of the Long Island Automobile Club, has appointed as chairmen of the various standing committees for the year 1908 the following members: Dr. William P. Richardson, membership; J. H. Emanuel, Jr., finance and auditing; Edward Melvin, house and entertainment; Arthur R. Pardington, vice-president and general manager of the Long Island Motor Parkway, contest; Leffert Lefferts, runs and tours; Dr. William P. Richardson, law and legislation; Louis T. Weiss, technical; Samuel H. Burns, good roads, and Dr. A. C. Howe, garage. Owing to the fact that the next regular meeting falls on Christmas day, it has been postponed to the day following. A ladies' night will be held at the clubhouse on Friday, December 27, the feature of the evening being a specially planned vaudeville show.

LATEST ADDITION TO THE FIRE FIGHTING AUTOS OF BOSTON—A KNOX FOR THE PROTECTIVE DEPARTMENT.

## BOSTON'S FIRE DEPARTMENT NOW HAS SEVEN AUTOS

**B**OSTON, Dec. 23.—There was put into operation in this city Saturday an unique piece of automobile fire apparatus, which, it is believed, will greatly strengthen the department and add materially to the fire protection of Boston. This most recent addition to Boston's fire-fighting equipment is a wagon built for the Protective department by the Knox Automobile Company, of Springfield, and delivered by the Reed-Underhills Company, local agents for the Knox.

The new wagon has a Model G Knox chassis with heavier springs than are used in the touring cars, five-inch Fisk tires all around, and an auxiliary gasoline tank with special cut-offs, so that the auxiliary tank may be used for starting. The motor is of the four-cylinder, 35-40-horsepower, air-cooled variety, with magneto and dry cells.

The wagon has a seating capacity for four men, two on the driver's seat and two on side seats in the rear, but if necessary eight men can be carried. In a large box behind the driver's seat are carried eighteen large rubber blankets such as are used to cover goods for protection from fire and water. In another box under the running board in the rear is a life net. The other

equipment includes axes, ceiling hook, plaster hook, two extinguishers, two five-foot extension ladders, sprinkler boxes with heads and tools, a Detroit door opener and other tools. The ladders are carried on leather-covered brackets on the sides and the other tools are stowed away conveniently on the sides of the body and in a box between the rear side seats.

With the new protective wagon the Boston Fire Department has seven pieces of horseless apparatus. There are two horseless engines driven by steam, the Ross steam touring car used by the chief in responding to alarms and in making his trips of inspection about the city, a Columbia, used by one of the assistant chiefs; an Oldsmobile used as a general utility car, and a Baker electric for the personal convenience of Commissioner Wells. The commissioner is a thorough believer in automobile fire apparatus and is introducing it into the regular department as rapidly as his appropriation will permit. He is especially favorable toward the use of automobile chemical trucks and may construct one of these in the shops of the department. Taken all in all, the Boston Fire Department has thus shown itself to be one of the most progressive in the country.

## MR. FRANKLIN, OPTIMISTICALLY, TO HIS DEALERS

**T**HE conservative element among American automobile manufacturers finds little to fear in the financial situation, to judge by the statements being issued by the heads of the big concerns. A sane and significant comment on the present status of the industry comes from H. H. Franklin, president of the Franklin Mfg. Co., of Syracuse, N. Y., in a letter to his dealers, in which he says:

"Many ugly rumors are in circulation in regard to the condition of various automobile concerns. Generally these rumors have turned out to be entirely without foundation. While it is true that all kinds of business enterprises, to say nothing of the banks, are subject at this time to unfounded attacks by the thoughtless, the automobile business seems to come in for more than its share.

"Now, all this wild talk is harmful. It tends to destroy confidence, and will have a damaging effect upon your future sales. It seems to us, therefore, that it is important and that the automo-

ble dealer owes it to himself to do what he can to build up confidence. If stories come to you that any automobile concern is in financial trouble, or is going to fail, or is in any bad way, you should take it upon yourself to verify the stories before giving them any credence whatever.

"Do not think for a moment the automobile business has come or is coming to an end. In our opinion it, as a business, is not suffering more than any other business. We admit that some phases of the automobile business have run their course and are now down and out.

"To continue in business, the automobile dealer and the automobile manufacturer will have to come down to earth and do business on a strictly business basis. The automobile that people are going to buy will have to be built along sensible and reasonable lines. The expensive, heavy, overrated motor cars are going out of fashion. Automobiles of light weight, medium price, and conservative power rating will be the enduring type."

## ABOUT EMPLOYING THE ENGINE AS A BRAKE

By BENJAMIN BRISCOE, PRESIDENT OF THE MAXWELL-BRISCOE MOTOR CO.

BY having the engine turn over against its own friction and other resistances, the motor may often be used as an exceedingly efficient means of braking the car in descending steep grades. Although in most cases the ordinary brake on motor cars would be sufficiently powerful to hold the car, the amount of friction involved will result in considerable wear upon the brake surfaces. Many motorists, therefore, when going down a hill, retard the progress of the vehicle by throwing in the clutch, with the low speed engaged, thus letting the onward movement of the car turn the engine over against its own compression. This, of course, requires considerable power, and therefore results in a powerful braking effect. However, in braking the car with the engine care should be exercised, and no motorist, unless he is fully familiar with the operation of his car, should do it.

In investigating the exact source of the braking action of the engine, when driven by the car under the circumstances cited above, the question arises whether the braking power is greater when the valves are closed than when they are open. Since the air taken into the cylinder upon each suction stroke must be com-

pressed on the next stroke, a considerable degree of resistance must be overcome—hence the braking effect. At the same time it has been asserted that the braking effect thus secured is very nearly rendered useless by the release of compression and the consequent expansion of the gas, which has given rise to the opinion that the resistance encountered by the air in being sucked in and expelled through the valve openings consumes more power and produces, therefore, more efficient braking. Other opinions lean to the theory that the friction set up in the various parts of the motor rather than the pumping action is the real source of braking. Be that as it may, the fact is that a motor when used in this manner makes a very good brake, saves the ordinary brakes and gives greater security to the operator in going down steep inclines.

Braking with the engine is not only gentle, but absolutely regular and particularly valuable when the ordinary brakes are wet and slippery, or overheated by continuous use.

A point to be observed is that the spark should be given again shortly before the end of the incline is reached, in order to start the power of the engine.

### EXHAUST MINGLES WITH ROAR OF GUNS.

PARIS, Dec. 14.—For the first time an automobile has been commissioned to take a place in the fighting line of an army. A few weeks ago the French army authorities secretly fitted out a Panhard automobile with a Hotchkiss quick-firing gun and sent it to Oran to wait instructions. At the same time Captain Genty was given sealed orders to proceed to Algeria within twenty-four hours, where he found the machine awaiting him with instructions to take it to the fighting line around Casablanca, for operations against the rebellious tribesmen. Probably no better commander than Captain Genty could have been found in the army, for he has been connected with automobiling since its earliest stages, has competed in international races and won records for Darracq and Bayard-Clement under the title of De la Touloubre. Lately he has been at the head of the army automobile transport service near Paris. His car is a Panhard, the tonneau being modified to receive its quick-firing gun.

One man at least is displeased with the choice of the fighting unit and has written to that effect to the Minister of War. The C. G. V. firm produced a special armored war automobile over a year ago and induced the Russian Government to take a dozen of them. Now Ferdinand Charron would like to know why Minister of War Picquart is risking the lives of brave troopers in an open automobile that has nothing whatever to recommend it, when for the sum of \$9,000 he could have a steel armored car, tires and spare parts included, to be returned at the end of a month if it was not satisfactory. But General Picquart has made up his mind that the open Panhard is good enough for him and after one official "declined with thanks" has silenced Charron with a curt note that he does not want what the Russians have got anyway. The reports of the influence of Hotchkiss bullets and Panhard exhaust on fanatical tribesmen is being awaited with some interest.

### LIGHTING TO BE DISCUSSED BY A. S. M. E.

At its next regular monthly meeting, which will take place in the Engineering Societies Building, 29 West Thirty-ninth street, New York, on January 14 next, the subject for discussion by the American Society of Mechanical Engineers will be "Car Lighting," a paper having been prepared by R. M. Dixon, president of the Mississippi river, which is saying a great deal. Reading of the paper will be supplemented by exhibits.

### OHIO AUTOISTS MOVE FOR UNIFORM LAW.

CINCINNATI, Dec. 23.—Acting in conformity with the recommendation of the American Automobile Association on the subject of uniform legislation, the Ohio State Association has taken the first steps looking toward action of this kind in their State by approving the proposed law drafted by the three A's for introduction at the sessions of all the State legislatures. The legislative committee of the State Association met at the offices of Chairman William Walker Smith, Jr., and Mr. Smith presented a letter from the State Attorney General, Wade Ellis, giving an informal opinion to the effect that the proposed law is constitutional and contains none of the defects which rendered invalid the State law passed last year.

The proposed measure covers the question of a single State license, registration of chauffeurs, reasonable speed restrictions and penalties for chauffeurs who accept bribes, or companies who offer bribes to chauffeurs, to have their supplies used on cars. The license fee is placed at \$5, and the chauffeur's registration fee at \$2, while makers will have to pay \$10 for each type of car manufactured. No definite speed limit is mentioned, the provision being that automobiles shall not be operated on the public highways at a speed "greater than is reasonable, having regard to the width, traffic and use of the highway and to the general use and rules of the road, or so as to endanger property, or life, or limb."

### KANSAS CITY'S SHOW DATES ARE FEB. 3-8.

KANSAS CITY, Mo., Dec. 23.—Convention Hall, this city, will be the scene of the annual automobile show of the Automobile Dealers' Association of Kansas City, and the week of February 3 has been set for the occasion. Convention Hall is one of the largest public buildings in the United States, with a floor space almost equal to that of Madison Square Garden, in New York, and the Coliseum in Chicago. Last year's show was a great success, and the coming year's exhibition promises, from the early manifestations, to eclipse in every way the 1907 exhibit. W. L. Walls, the secretary of the show committee, is actively engaged in the work of preliminary preparation, and has issued plans of the building to intending exhibitors. The local trade is enthusiastically working as one man for the success of the show, which promises to be the biggest thing of its kind ever held west of the Mississippi river, which is saying a great deal.

### MATERIALS FOR THE HOME BUILDER.

Probably nine out of ten autoists with a mechanical turn of mind have thought, at one time or another, that they would like to build a car of their own, and a great many have actually done so during the past few years. In fact, the demand for automobile components on the part of those not directly concerned in the building of cars for the market has become such that a firm has entered the business of catering to it. This is the Howard Motor Works, Yonkers, N. Y., who build the well-known Howard motors, one of the six-cylinder types of which is illustrated by the accompanying photograph. The material is designed to build a six-cylinder chassis, and the parts, in addition to the motor already referred to, are of the best grades turned out by various well-known makers in this country. A tubular front axle is supplied regularly, although an I beam drop-forged type will be provided at a slight additional cost; springs are of the semi-elliptic type at all four points and are of liberal dimensions, while the wheels measure 34 by 3 1-2 inches, though four-inch rims will be supplied to order. The frame is of the best pressed steel construction and is designed to give the car a 110-inch wheelbase with standard tread. It also embodies a sub-frame with four-inch drop, all spring hangers being drop-forged and extending up to the cross member; it is supplied

INTAKE SIDE OF THE HOWARD SIX-CYLINDER ENGINE.

complete with the spring links. Other materials provided are the steering gear, propeller shaft, side levers, clutch, connections, pedals, brakes, radiator, fan, hood, steel dash and all bolts and nuts for completing the work of assembling. The complete materials are offered at \$1,200, including blueprint as a working guide.

### SHAFT ALL THAT REMAINS OF "LA PATRIE."

PARIS, Dec. 14.—One material souvenir of the military airship *Patrie* remains to the French authorities. After crossing the English Channel, the ship drifted over Wales, crossed the Irish Channel, then hovered over County Down, Ireland. Some of her gas had escaped during the trip across sea, with the result that in the hilly district of Down the *Patrie* struck earth several times. A few miles south of Bangor the *Patrie* dragged along the ground, went through a stone wall and lost part of her car. Veering towards Belfast Lough, she prepared herself for another sea trip by dropping her propeller shaft and gear box on Farmer Macfarlane's land, near Craigavad. It was the last of the *Patrie*, for, freed of this weight, she appears to have skirted the Scottish coast and to have passed to an unknown grave in the Atlantic. Souvenir hunters rushed in haste to neighbor Macfarlane's place, but received little for their pains, for a War Office official was already on the spot to take charge of all that remained of the world's finest airship and return it to its sorrowing owners.

THE FIRST SELDEN "28" UNDERGOING ITS TESTS.

### CHRISTIE PROMISES FRONT-DRIVE TAXICABS.

Since his accident on the race track during the past season, Walter Christie has been paying renewed attention to the production of a taximeter cab on his front drive principle. From the drawings, now in an advanced condition, the new vehicle possesses a number of special features which should make it particularly economical to operate and maintain in the rough service for which it is intended. Mr. Christie retains the basic design of a front drive and front steering developed for several years on his racing cars, with certain improvements suggested by experience, and modifications for city work. Compactness and accessibility are obtained to the highest degree by carrying the four-cylinder motor, transmission and all mechanical parts forward of the dashboard, this position also allowing reduced wheelbase and easier turning.

### COLT RUNABOUT COMPANY INSOLVENT.

A petition in bankruptcy has been filed against the Colt Runabout Company, 1876 Broadway, New York, by the Frank Presbrey Company, \$1,300; Robert Bosch, New York, Inc., \$400, and the Reliable Radiator Company, \$174, on the ground that the company on December 19, and while insolvent, transferred some of its property to Kane & Robinson, and a Mr. Gillette, two creditors, to prefer them. The concern was incorporated on June 3, 1907, with a capital stock of \$10,000, which was later increased to \$50,000. A factory was established at Yonkers, N. Y., and the company began to turn out a six-cylinder car of the runabout order, using the Howard motor. Harry Osterman has been appointed receiver by Judge Hough of the U. S. Court.

MR. AND MRS. C. A. BENJAMIN, OF DETROIT, IN 1908 AEROCAR.

THE CLEVELAND ASPIRES FOR HONORS AT ORMOND MEET.

James Laughlin, 3d, and Charles G. Percival, publicity manager of the Cleveland Motor Car Company, in the 1908 Cleveland Car that will race in Florida.

### BOSTON'S Y. M. C. A. SCHOOL SUCCESSFUL.

BOSTON, Dec. 23.—An interesting demonstration of the possibilities of an automobile, outside its capabilities as a vehicle, was given one evening last week at the new White garage on Newbury street. The Y. M. C. A. automobile school, which, by the way, is the oldest automobile school in this country, was holding its mid-winter social gathering, and as music was desired it was decided to try some automobile music. A car was fired up and by means of a belt the power from a rear wheel of the car was transmitted to a hurdy-gurdy. As far as operation went the results were excellent. From a musical point of view the results were somewhat marred by the mechanical interest of the operator who tried at times to see how much acceleration the hurdy-gurdy would stand. Another interesting experiment was the belting up of the other driving wheel of the car to a wood saw, thus demonstrating how the farmer owner of a machine may put it to work sawing the winter's supply of kindling wood.

There were two instructive competitions in which students of the automobile school participated. The first was a tire drill. Four men were seated in a car. At a signal they sprang out, secured jacks and lifted the wheels. Then they removed the casings and inner tubes, replaced the tubes and put back the casings, the one doing it in the shortest time receiving a prize. The other competition was an ignition drill in which the competitors were sent hunting for ignition troubles, the one starting his engine first being given a prize.

### AMERICAN TIRE MAKERS INVADE EUROPE.

As an offset to the establishment of branches of foreign tire factories in the United States, the B. F. Goodrich Company, of Akron, O., is going abroad to get its share of the foreign trade. Goodrich tires are already well-known in France, an agency established in Paris some time ago having done a good business. Now a branch house is to be opened at number 2, Rue Brunel, Paris, and a full stock of tires and appurtenances carried so that the American makers will compete with the French manufacturers right on their own ground, and American tourists on the other side will also find it easy to replenish their supplies. The branch will be in charge of Mr. Lumsden, the European manager of the Goodrich interests.

### TIRETOWN HAS ITS FIRST AUTO SHOW.

AKRON, O., Dec. 23.—Akron's first automobile show last week, conducted by the Akron Automobile Garage Company in its new garage, was a complete success and was attended by several thousand people. As an outgrowth of this exhibition, it is hoped that the show will become an annual affair. Some interesting machines were on exhibit, among them being the first horseless carriage built in America, described by a sightseer as "a vehicle

that looks like the result of a collision between a miniature traction engine and a buggy." The builder was Achille Phillon, of this city, who put the machine out in 1889. It has an upright steam engine at the rear, with a 2 1-2-horsepower motor which, when first built, burned coal. "The Mudlark," driven by R. R. Owen and Andy Auble to Florida from New York a year ago, and "Red Cloud," used by Fred Work and H. J. Maxson for their transcontinental trips, were also on exhibition.

### NEW FIRM TO MAKE IGNITION SPECIALTIES.

PITTSFIELD, MASS., Dec. 23.—The Jacobson-Brandow Company is the title of a new concern that has been organized here to begin the manufacture of patented ignition specialties. The incorporators are Edward B. Jacobson, formerly superintendent of the Pittsfield Spark Coil Company, and Dr. Frank B. Brandow, an enthusiastic autoist, who has several inventions to his credit. Some of these are the Brandow combination lock switch and the Brandow "spark indicator." The firm will also manufacture a spark plug of their own design and special construction as well as a line of induction coils for automobile ignition. The latter are distinguished by the use of a very simple and easily adjustable vibrator, and also by a readily detachable condenser. Quarters have been secured in the Dunham block and machine tools installed so that manufacturing is already under way. It was at first intended to market the product direct and manufacture on a conservative scale, but negotiations have been completed with the Pettingill-Andrews Company, of Boston, to handle the entire output and the facilities of the concern will be increased accordingly. The company will establish a factory here.

### NEW B. & S. SPRING STEERING CONNECTION.

Recognizing that, in the ideal steering gear, vibration must be eliminated to the last degree, if crystallization of the metal of the various components of the gear is to be prevented, the Billings & Spencer Company, Hartford, Conn., makers of the well-known B. & S. steering connections, are putting out a new spring type of their own design. In addition to the spring arrangement, it also embodies a simple and highly effective locking device, which secures the steering arm to the connection, making it proof against parting at this vital point. This new

DETAILS OF NEW B. & S. SPRING STEERING CONNECTION.

connection consists of an outer case, A, surrounding a ball and socket joint B, to which is attached a lug passing through a helical spring, as illustrated in the accompanying line drawing. Washers are placed at each end of this spring, while a nut at the end of the lug binds these parts together. This piece is inserted into the end of the case A, after which the ball-arm is placed in position through a hole in the side of the case, and secured by the castellated plug, G. The slotted sleeve, E, is then inserted in the end as far as the washer, D, surrounding the ball and socket. The whole is then secured by the castellated and threaded plug, F, which is further secured by a cotter pin and binder lug.

From the shoulder at C, vibration in one direction acts upon the spring at the washer, C, and in the reverse, at the washer, D, through the sleeve, E, which is held by the plug, F. This sleeve has a longitudinal slot just wide enough to pass over the neck of the ball-arm after the latter has been placed in its socket and secured, thus preventing the ball-arm from becoming detached, should G become loosened or worn. The new B. & S. connection is made for 1 1-8-inch ball.

## BRIEF ITEMS OF NEWS AND TRADE MISCELLAN

Ashton Valve Company, of Boston, is now making a complete line of pressure gauges for gas tanks.

The Whitten-Gilmore Company, which represents the Thomas cars, has opened new salesrooms at 907 Boylston street, Boston. George Crittendon, formerly with the Premier Company, has joined the selling force.

D. P. Nichols & Company, 121 West Brookline street, Boston, well known in carriage circles, have fitted up one of the best and most modern plants in New England for overhauling, painting, repairing or renewing worn parts of automobile bodies.

The Munson Steamship Company and the Quebec S. S. are the latest addition to the constantly increasing number of companies who are allowing gasoline motor trucks the same unrestricted access to their piers as horse-drawn trucks. This is a matter that the New York Automobile Trade Association has been advocating for the past few months.

T. A. Quinlan, Jr., president and general manager of the Monarch Motor Car Company, Chicago Heights, Ill., announces that the formal opening of the new factory at the above address will take place on January 2. A noticeable feature in connection with the plant is the testing track, which is built on an adjoining tract of land, covering about four acres. Paul Symonds has been appointed sales manager.

That 13 is not invariably an unlucky numeral is attested to by R. E. Hardy, president of the Motor Parts Company, 25 West Forty-second street, New York. The company is composed of thirteen men and commenced business last March with an authorized capital of \$100,000. It carries complete lines of gasoline motors, transmissions, differentials, lamps, springs, coils and all kinds of ignition accessories, and has built up a very successful selling organization.

The makers of the Michelin tires take considerable pride in their record as purveyors to every crowned motorist in Europe, namely, the King of England (Daimler car), King of Italy (Fiat car), Queen Dowager of Italy (Fiat car), Emperor of Russia (Darracq car), Emperor of Germany (Fiat car), King of Spain (Panhard car), King of Portugal (Peugeot car), Shah of Persia (Serpellet car), and the President of France (Panhard car). By the establishment of their new American plant, where Michelins will be made identical in materials and construction with the foreign product, they cut out all costs of duties and trans-Atlantic charge, with the evident intention of being "purveyors to the American citizen in general."

To meet the demand of manufacturers and owners of light cars, the Hartford Suspension Company, 67 Vestry street, New York, have just perfected what will be known as the "Truffault-Hartford Junior." This newcomer is practically a replica of the standard pattern of Truffault-Hartford shock absorbers, embodying all the essential features of the latter, the chief difference being in its size. It is intended to be fitted to such runabouts as the Ford, Maxwell, Mitchell, Reo, Buick, Atlas, Cadillac and cars of similar size and type, and lists at \$25. It has been placed on the market as the result of a strong demand which has

manifested itself recently and particularly at the New York and Chicago shows. Three models of the Truffault-Hartford shock absorbers are now manufactured, so that the makers are in a position to supply them for any size car.

Harry D. Miller, president of the Bridgeport Vehicle Company, builders of automobile bodies, at Bridgeport, Conn., has formulated a plan for reducing the maintenance expenses of autoists in his city and has accordingly established an annual contract service. This includes taking entire charge of the car, keeping it in repair and commission, and thus doing away with all the petty garage annoyances which the average owner finds himself subjected to continually. The cars will be thoroughly examined at least once a month, the annual charge being \$75, payable semi-annually in advance. In addition to the regular inspections, the service will include all repairs necessary between inspections, a report being sent after each calling attention to parts that are worn and require replacement. Such parts will be supplied at factory cost and there will be no extra charge for their replacement on the car. Oil and gasoline will be supplied at the usual rates.

## NEW AGENCIES ESTABLISHED.

The Tincer Motor Car Company, of South Bend, Ind., have opened a Chicago branch in the building of the Chicago Automobile Club, on Plymouth place.

E. S. Partridge, of Wyckoff, Church & Partridge, Broadway and Fifty-sixth street, New York, has been in Boston for several days past in the interests of the Stearns line and will complete negotiations for the opening of an agency of the Stearns car at the Hub before returning.

Paul Lacroix, American representative of Renault Freres, announces that a Chicago agency for the Renault cars will be established in that city in the near future. It is also expected that plans for western representation include an agency on the Pacific coast, which will doubtless be located at San Francisco.

After January 1, 1908, the branch of the Hartford Rubber Works at 88 Chambers street, New York, will be discontinued, direct representation of the Hartford office being then centered in the uptown branch, located at Fifty-seventh street and Broadway. Although the latter branch has been at the same address, known as the "tire corner," for a number of years, the building has been reconstructed and the company has taken considerably more space to keep up with the demand for Hartford tires. Charles E. Miller, 97 Reade street, has been appointed as downtown agent in New York.

## PERSONAL TRADE MENTION.

Alvan T. Fuller, the Packard representative for Boston, has gone abroad on a three months' vacation.

Petr C. Rutan, formerly of the P. C. Rutan Company, Port Jervis, N. Y., will open a store and garage at 46 Front street, that city, on January 1, and will deal in automobiles, bicycles and sporting goods.

The Hotchkiss cars will be represented in Boston by Milton Kent, a newcomer in

the auto field. Salesrooms are now being fitted up on Boylston street in premises recently vacated by the Butler Motor Car Company.

R. D. Aldrich is now connected with Brandenburg & Company, 85 Lake street, Chicago, the well-known selling agents of automobile parts, and will handle the central western territory, with Chicago as headquarters.

H. C. Mills, formerly with the Pittsfield Coil Company, has joined the selling forces of Pettingell-Andrews Company, Boston, exclusive selling agents of the Jacobson-Brandow Company, Pittsfield, Mass. Mr. Mills will start on his Western trip January 1.

R. H. Combs, manager of the Chicago Battery Company, 3685 Olive street, St. Louis, Mo., is an old-time newspaper man, but for the past four years he has devoted his entire time and attention to the subject of electric ignition and lighting for the automobile.

A. O. Hunter has been appointed manager of the Chicago branch of the Franklin Automobile Company. Mr. Hunter was formerly head instructor of salesmen for the National Cash Register Company, at Dayton, O., and prior to that time was instructor of salesmen and salesman in the Chicago territory for the National people. He has a wide acquaintance with Chicago business men.

E. Le Roy Pelletier, for some time past associated with the Ford Motor Company, and whose publicity work has attracted universal attention, suddenly resigned his position as advertising manager a few days ago. Mr. Pelletier's decision to sever his connections with the company with which he has been identified so long was made very suddenly and solely with a view toward his own advancement, though he did not wish to announce any definite plans for the immediate future, other than that of taking a much-needed rest for a few weeks. In recognition of his splendid services for the newly organized Detroit Automobile Dealers' Association in carrying off their first Detroit show of a few weeks ago with such brilliant success Mr. Pelletier was presented with a handsome solid gold stop watch.

F. A. Babcock, president of the Babcock Electric Carriage Company, Buffalo, N. Y., has just returned from a flying four-week trip abroad. He left New York on the *Lusitania* when she made her record-breaking eastward trip, spent two days at the Olympia show in London, then leaving there for Paris, he put in a week at the Salon, returning to New York again on the *Oceanic*. Mr. Babcock declared that the fact which impressed him most forcibly at both shows was the absence of runabouts of the electric type, and he thinks there is a great field for these vehicles in both England and France. In the electric field he found that only landaus, landaulets and broughams are used, and these are employed almost entirely for public hire. There were three cars of American make at both the London and Paris shows, the demand being greatest for the small car having 18 to 25 horsepower. The Paris Salon, Mr. Babcock thinks, was, without doubt, the greatest exhibition of automobiles ever held.

### Cars for Sale

**ABSOLUTE** closing out sale of the largest stock of new and second-hand automobiles in the United States; write for Clearance Sale List No. 20; now is the time to buy. Rochester Automobile Co., Jos. J. Mandery, Prop., Rochester, N. Y.

**A BARGAIN**—1907, 20-h.p., 4-cylinder Model G Cadillac runabout; best of condition; demonstration at any time. Address Morgan & Wright, 214 West 47th St., New York.

**AUTOMOBILES**—30-h.p. Pierce-Arrow, 1906, \$2,000; 24-h.p., 4-cylinder Ford, \$600; 26-h.p. Rambler, \$700; 50-h.p. Thomas Flyer, \$1,500; Cadillac delivery car, \$350; 30-h.p. Model H Cadillac, \$1,500; 30-h.p. Peerless, \$1,000; these are great bargains, but must be sold. E. R. Clark Auto Co., 461 Worthington St., Springfield, Mass.

**AUTOMOBILES** at your own price. We have a complete assortment of slightly used and second-hand automobiles which will be sold regardless of their value, as we MUST have the room; positively the greatest opportunity ever offered; come early and secure a bargain. If you cannot come personally, communicate with us at once. The Starlin Company, 1094-1100 Main St., at St. Paul St., Buffalo, N. Y.

**BARGAINS**—Packard touring, 1906, \$2,350; Ford runabout, top, \$400; Thomas touring and limousine, \$1,200; 6-cylinder 1907 Ford, \$1,500. Vanderveer, Times Bldg., 42d St. and Broadway, New York City.

**BUICK MODEL F**—New; never used; regular factory equipment; 1907 model; regular price \$1,250; will take \$900. "A." care The Automobile.

**BUICK**—1907, with 1908 improvements; 4-cylinder, 24-h.p., new car; used but little, by very careful owner; a perfect running car; price, \$1,500, with extras (regular price now \$2,000, with \$100 more for extras). W. A. Russell, P. O. Box 2898, Boston, Mass.

**BUICK**—Four-cylinder, Model D; equipped with gas and oil lamps, gas generator, extra tire, Allen tire holders and tire cover, Veeder dash odometer, \$125 top complete; run 987 miles, and is as good as new; cost, as equipped, \$2,275; sell for \$1,350; guaranteed all O.K. "B." care The Automobile.

**FINANCIAL STRINGENCY** compels us to offer panic prices in Ford 6-cylinder, Franklin D. Maxwell H., and runabouts; Olds and Cadillac runabouts; it will pay you to write for list; we have bargains you can't duplicate. Automobile & Garage Co., Meyersdale, Pa.

**FLANDAU BROUGHAM**—Cost \$1,500 when new; only been run a short time; also new Victoria, never has been run, worth \$1,000; for sale, or will exchange for automobile high power gentleman's roadster. Address C. D. Jones, 701 Connell Bldg., Scranton, Pa.

**FORD RUNABOUT**—1907, Model N; nearly new; bargain. 252 Palisade Ave., Jersey City, N. J.

**GET WISE**—We have anything you want in second-hand cars—Packard, Winton, Locomobiles, White steamers, Franklins, Buicks, Oldsmobiles—and bargains at that. Get our list for March. The Sid Black Automobile Co., 630 Walnut St., Cincinnati, Ohio.

**HOLSMAN**—1907 Model 9; top, storm front and detachable rear seat; \$500. L. M. Lowe, Glyndon, Minn.

**LARGEST** automobile dealers in the world; over 250 cars here on consignment, many of them are for quick sale, the owners being eager for quick cash. Now is the time to secure a bargain; call, phone or write for list. Runabouts \$100 to \$550; tonneaus and touring cars \$250 to \$5,500. Come, make bid and let us submit your offer to the owner. In this way you can secure an auto at a very low figure. Manhattan Storage Co., 334-340 West 44th St., New York City.

### GARFORD WEEKLY LIST OF SECOND-HAND CARS:

- 64—Packard runabout, 1907 model, used but few months; exceptional opportunity .....\$2,750
  - 65—Packard touring car, Model N; absolutely guaranteed; excellent condition 950
  - 66—Packard touring, 1906 model; excellent condition; very cheap..... 1,500
  - 67—Packard touring car, 1907 model; very good condition..... 2,600
  - 68—Cleveland chassis, 1907 model; suitable for touring; limousine, landaulette or runabout body; cheap; excellent condition; absolutely guaranteed ..... 1,000
  - 69—Rainier touring, 1907 model; good condition ..... 1,800
  - 70—Rainier limousine, touring 1906 model ..... 2,000
  - 71—Hotchkiss demi-limousine, 1906 model; fine condition..... 3,400
  - 73—Decauville touring, seating seven.. 750
  - 74—Dorris, 30-35, 1907 model; two months old ..... 850
- Also cars of many other makes at from \$500 up. The above cars have been placed with us for sale by parties ordering Garford cars. In making inquiries kindly mention serial number of car you may be interested in. Garford Motor Car Company of New York, 1540 Broadway, New York City.

**ONE EIGHT-PASSENGER** touring car; tires practically new, 5-inch on rear, 4-inch front; cost to build, \$3,500; sell for \$350; guaranteed in first-class condition. "D." care The Automobile.

**PACKARD MODEL L**—Run only 6,000 miles; exceptional condition; full equipment, except top; Rushmore searchlights. For information address Box 466, Jacksonville, Fla.

**PACKARD CARS** for sale—Packard cars in good condition at moderate prices, by people who have ordered 1908 Garfords. Inquire Garford Motor Car Co. of New York, 1540 Broadway, New York City.

**PIERCE GREAT ARROW**—1906 model, 32-h.p., perfect condition; cost, with equipment, \$4,600. Address 72 Weissinger-Gaulbert, Louisville, Ky.

**POPE-HARTFORD** touring car; side entrance; top, lamps, horn, etc.; used one season; fine condition; will sell for \$900, if taken at once. Lanpher Bros., Carthage, Mo.

**POPE-TRIBUNE RUNABOUT**—New; 1-cylinder, 6-h.p., 1905; 2 speeds and reverse, 750 pounds; easy riding, reliable, good power; \$200; cost \$500; reason, use touring car. H. M. Rich, Morrisville, Vt.

**POSTAL AUTO BUGGY**—With top; run 200 miles. Ed. Tetzl, Terre Haute, Ind.

**RAINIER LIMOUSINE**—35-h.p., 1907 model, Burr body; in first-class condition; seats six; price \$2,800. Diefenderfer, 244 West 49th St., New York.

**RAMBLER TOURING CAR**—25-h.p., 4-cylinder, with complete equipment; 1906 model; to be sold at a sacrifice. Address Box 656, Waterbury, Conn.

**REO RUNABOUT**—Also Reo touring car; fine condition; bargains. 2395 Boulevard, Jersey City, N. J.

**ROYAL TOURIST**—\$1,500; side entrance; best condition; top, trunk rack, new extra tire in carrier, two 4-cell storage batteries, complete lamp equipment, clock and speedistmeter. Bickford, 233 Alexander St., Rochester, N. Y.

**SIXTEEN-SIX WINTON**—New, 6-cylinder, 50-h.p.; this car will be sold at a sacrifice if taken immediately. Address "Sixteen-Six," care The Automobile.

**STEVENS-DURYEA**—1906, 4-cylinder touring car; good equipment; extra low price if sold at once. J. S. Harrington, 36 Central St., Worcester, Mass.

**HOW TO RUN AN AUTO**

Are you Interested in Automobiles?

If you are, an early purchase of "HOMANS' SELF PROPELLED VEHICLES" will prove a good investment.

This work is now the accepted standard on the practical care and management of motor cars—explaining the principles of construction and operation in a clear and helpful way, and fully illustrated with many diagrams and drawings.

The presentation of subjects has been determined by consideration of the needs of the man behind the wheel. It is clear and concise in its treatment, and comprehensible to the most inexperienced automobilist, at the same time it is as thorough that the

expert will learn much from its pages. This good book will be sent to any address in the world, postpaid, upon receipt of two dollars, or if desired, will be sent on approval to be paid for after examination. Contains 608 pages, over 400 diagrams and illustrations, printed on fine paper, size 5 1/2 x 8 1/2 inches, with generously good binding. Highly endorsed

No money in advance required, return and name. Theo. Audel & Co., 63 Fifth Ave., N. Y. Kindly mail me copy of "HOMANS' SELF PROPELLED VEHICLES" and if found satisfactory I will immediately remit \$2.00 for return book.

**The Ideal Ignition Equipment**

If a coil is used, consists of a Dow Coil, Dow Double Insulated Mica Spark Plugs and a Dow Ball-Bearing Timer. If a magneto is preferred, the Dow "KOMET," in which the distributor and timer are incorporated, will give you more efficient service and less trouble than any other. The "KOMET" is an **IGNITION INNOVATION.** Write for particulars.

Dow Double Electric Co., Framingham, Mass.

**Every Day Use of a 1908 Solar**

will be a constant and increasing source of gratifying assurance to its owner that he has exercised most excellent judgment in the purchase of this lamp for durability and quality of service.

Retaining the features that have won for them the approval of highly competent and critical judges, the 1908 Solars offer four (4) Exclusive features for the season. Write for our *Exclusive Feature Book.*

There's a Good Reason  
for the Popularity of

# Hartford Tires

- Owners have learned by expensive experience that, of all things, **quality** in automobile tires is the first, last and **only** thing to consider.
- It has taken a long time and a hard, persistent and expensive campaign to bring this result about.
- But this factory has never faltered in its policy for a minute, not even for a second. We knew that "quality" would win, and it has most handsomely.
- Hartford Tires and Midgley Universal Rims predominate at the National Automobile Shows, not only on the big, expensive, luxurious, "classy" cars, but on the best medium priced cars, and on the leading low priced cars as well.
- The way Hartford Midgley Tread Tires have forged to the front marks an epoch in tire making. No non-skid device compares to it in efficiency, utility, in appearance or sales. It is the only safe, sane, sightly and practical non-skid tire.
- Your old enemy, the "Tire Bugaboo," will not mar your pleasure or "dent" your pocketbook if you will decide right now to have the best tires money can buy—Hartford Tires. We make Hartford Clinchers and Dunlops, Hartford Midgley Tread Tires in both Clincher and Dunlop, and the new Hartford Quick Detachable Clincher.
- Better let us send you our new tire catalogue, a Midgley tread booklet, and a little folder just out, "How to Put on a Clincher Tire."

A Book Indispensable to Automobilists in Making One-day and Two-day Trips from New York City

Actual Size,  
5 1-2 x 9 1-2 inches.

## The Metropolitan Automobile Guide

Covering the territory within a radius of 75 to 100 miles of *New York City and vicinity* with completeness and accuracy never before approximated.

**74 COMPLETE ROUTES—EVERY ROUTE A ROUND TRIP**

**6737 1-2 Miles. 382 Pages.**

Accompanied by City Diagrams and Route Maps, together with best accommodations in Hotels and Garages. Exact mileage given for every town and every turn and landmark on the routes.

**FULLY ILLUSTRATED AND DESCRIBED BY TEXT.**

### THE PLAN AND PURPOSE

THE METROPOLITAN GUIDE is a SPECIAL volume devoted to the territory practically within a hundred miles of New York City, though a few of the routes extend in a longer radius. It is meant for the Autoist who wishes COMPLETE touring schedules FROM and BACK TO NEW YORK CITY in sufficient variety to cover any section of the country in any way, with State lines practically ignored.

The territory covered, in brief, is New York City and immediate vicinity, with routes extending to Newburgh, Poughkeepsie and Pawling on the North; Danbury, Waterbury and Bridgeport on the East, including all Long Island routes to Greenwood Lake, N. Y., the Ramapo Valley, N. J., Morristown and Bernardsville on the West, and with extensions to Princeton, Lakewood and the North Jersey Coast to the South and West. The routes are uniformly in pairs, enabling any one of the same to be taken in either direction.

One great advantage of THE METROPOLITAN GUIDE is that each trip is planned throughout for the Autoist so clearly and precisely that he can easily travel without asking a single question; at the same time, by merely setting his odometer to correspond, it is possible to pick up the route at any intermediate point.

How It Clears the Road.  
Why Never Out of Order.*  
You may have the roar of a lion or the purr of a kitten. You get the road to yourself. Everyone turns out and gives you the right-of-way. Beautifully finished in polished brass and aluminum. An ornament to any car.  
**Stewart & Clark Manufacturing Company**  
806 Diversey Boulevard, Chicago, Illinois.

## THE LEAVITT Improved Wipe Contact Timer

To meet a demand for a wipe contact timer we have improved upon the well-known Lacoste Timer by adding a supplementary ground terminal and an adjustable ball-bearing in place of the plain bearing. This eliminates the two principal faults of this timer, i.e., poor ground and wobbling after running a short time, both of which will cause skipping when running at high speed. The above faults are usually ascribed to the plugs, coils or carburetor.

# "CLEANOLA"

## SAMPLE FREE

We want to convince every car owner, chauffeur, manufacturer and dealer in the United States that

### "CLEANOLA" OIL POLISH

is superior to anything in the world for cleaning, brightening and renewing the fine finish, and restoring the surface and "shine" of the varnished wood and metal work, leather trimmings, cushions and tops of your car after each run, and giving them the surface and finish they wore when new, thereby prolonging their life and greatly improving their appearance. If you are not already a user of "CLEANOLA" we will send you a sample free of any expense to you, that you may test its value and prove our claims.

Write to-day. A request carries no obligation. All inquiries answered promptly.

The Cleanola Company Dept. 53 W. Van Buren St., Chicago

## MOTORS AND MOTORING

By HENRY J. SPOONER, C. E.

THIS is undoubtedly the best book for the owner or intending purchaser who desires to get a good practical idea of the how and why of automobile construction and operation without having to read a great mass of highly technical literature. It is written in a simple condensed style and the text is well illustrated by diagrams. A work vastly superior to the numerous cheap and inaccurate compilations on the market. In cloth covers, 113 pages, 5x7 ins.

Price, One Dollar, Postpaid

The CLASS JOURNAL COMPANY  
Flatiron Building New York City

# Pittsburg Six

## FOUR MODELS

# MICHELIN

FRANCE. ENGLAND. ITALY. AMERICA.

**T**HE use of tire chains has been prohibited by law in New Jersey, in many of the best motoring sections of New York, and pending legislation promises to make general the restrictions on their use. At the best, tire chains were but a makeshift, liable to be harmful in the end to the tires they were meant to save. The most effective and most practical preventive of skidding is the

## Michelin Clincher Tire, Anti-Skid Type

**M**ichelins can be used on any of the universal rims and on all of the world-known Detachable Rims

This Anti-Skid type, with steel rivets and LEATHER tread, sacrifices less of its resiliency than any other made, as the leather does not cover the side walls, but protects the wearing tread only, the side walls being the same and retaining the celebrated flexibility of the other Michelin types. In its qualities of durability and reliability it has a record placing it far beyond competition, as this is the type which was used on the winning car in the Vanderbilt Cup Race in 1906 and on the winning cars in all the world's important events from that time to date, except the 1907 Grand Prix in which the New Michelin Compressed tread on Michelin Demountable Rims was victorious.

Cross Section, Michelin Demountable Rim

Cross Section, Michelin Quick Detachable Rim, with rings used with quick detachable type tire

Cross Section, Michelin Quick Detachable Rim, with rings adaptable to clincher type tire

Interesting Propositions for Unoccupied Territory

## YOU SHOULD HAVE A "HANS" GASOLINE INDICATOR

ON YOUR DASH

**REASON 1.** Because it indicates the exact amount of gasoline in the tank at all times.

**REASON 2.** Because you will never be deceived as to measurement when buying gasoline, and you know at all times on tour how much you have in your tank and how far it will go.

**REASON 3.** Because the "HANS" Indicator is absolutely perfect in mechanism and operation, and so simple it cannot get out of order.

**REASON 4.** Because it is easy to attach and is an ornament to any car. The Gauge is just as necessary on motor boats as on automobiles, and is just as easily applied.

**REASON 5.** Because the material and workmanship are of the best.

**REASON 6.** Because it is not a luxury, but an absolute necessity.

The "HANS" Indicator is the Best Made

Write to-day for full particulars and prices. Sold by dealers and supply houses everywhere.

Renault — Maja — Delaunay-Belleville — Panhard  
 Motor Car Equipment Company  
 Robert Bosch — Auto Supply Company

# MAJA

Pronounced

"My-yah"

## The sister of Mercedes

is the latest improved product of the Daimler Motoren Gesellschaft, makers of the Mercedes cars, named by Herr Jellinek for his daughter, Miss Maja Jellinek, just as he named his earlier model for Miss Mercedes Jellinek.

The Maja Motor is the simplest, most powerful for size and the quietest in the world—exhibiting features that will as surely advance the art of motor-car making as did the previous revolutionary productions of these famous works.

For 1908 these advantages are to be had only by using a Maja car.

The Maja car is placed within reach of all lovers of good automobiles by marketing through direct branches of the parent Company, avoiding all middlemen and agents, charging one normal profit over the expenses of manufacturing, whereby the most costly models the Daimler works have ever made, become the lowest in price to the purchaser.

Full particulars from the American Branch of the Maja Company, Ltd., 230 West 58th St., New York. Tel.—1393 Columbus. Other Offices and Branches:

London, Paris, Stuttgart, Hamburg, St. Petersburg.

You are invited to attend "Maja's" debut at the Importers' Automobile Salon from December 28 to January 7, at Madison Square Garden, New York.

As is befitting, "Maja" has been assigned the leading position in the Show, immediately at the left of the main entrance. Space A1.

# RENAULT

**"The Car"**

**STYLE      SILENCE      SPEED      SIMPLICITY**

**All Over the World the Renault is To-day the  
Acknowledged Standard of Automobile Perfection**

In the famous 24-hour race at Morris Park the Renault, with a stock car and without a single adjustment, broke all world's 24-hour records for a single car in competition on a mile track, making 1,079 miles, defeating the nearest competitor by 107 miles

## PRACTICAL ARTICLES FOR THE AUTOMOBILISTS

### Smooth-On Iron Cement

The Smooth-On Iron Cements are chemical iron compounds, that withstand fire, water, gasoline, steam or oil. When hard they become a metallic iron that expands and contracts the same as iron. This makes them valuable for making many repairs. A few of interest to automobile owners are:

- Cracked Water Jackets,
- Leaky Radiators,
- Leaky Screw Thread Joints,
- Leaky Exhaust Pipes and Mufflers,
- Loose Nuts, etc.

Every automobile owner should carry a Smooth-On Repair Package. It contains a one-pound can of Smooth-On Iron Cement No. 1, a one-pound can of Smooth-On Elastic Cement and the Smooth-On Instruction Book, which tells when, where and how to use the different Smooth-On Iron Cements. The cost is one dollar, and it may save you many dollars' worth of time and trouble. Send for a package to-day. \$1.00 f.o.b. N. Y. City.

### Metric Wrenches

These wrenches are made of the best steel milled exact to given size, perfectly hardened and finely finished.

No.	Opening Small End	Opening Large End	Price
201	6 Millimeters	10 Millimeters	\$0.35
221	8       "	13       "	.40
231	11       "	16       "	.50

251	14       "	22       "	.70
261	20       "	25       "	.80

Price, complete set, \$3.00

### Combination Oil Can and Funnel

Allows the oil to be poured directly into any receptacle. Made in tin and copper.

Price  
Tin   Copper  
per  
1/2 pt. 20 65  
1 pt. 25 80  
1 qt. 30 1.10  
2 qt. 60 2.00  
1 gal. \$1 53

### Auto Ratchet Screwdriver

Makes it possible to operate on screws totally inaccessible with the ordinary tool. Has two blades. Quicker than regular screwdriver for ordinary use.

Price, \$1.50

These are a few of the many articles illustrated and described in our 112 page catalogue. Send for it.

## Blanchard Horns

21 Styles of the Highest Grade Horns

Have No Equal for Sound or Quality

They have the sound that made imported horns famous. Made by the famous musical instrument makers—Blanchard, of Paris—who are acknowledged to be the finest horn makers in the world. Our stock of horns is very complete, and we are prepared to suit the most exacting taste.

## The Le Janus Horn

The latest of the Blanchard family is the Le Janus, or two-faced horn. It has an adjustable swivel bracket, enabling it to be attached anywhere on the car, and always presenting a handsome appearance. Its peculiar construction gives it a deep sounding tone unequaled by any other horn.

Price .....\$21.00

## Copper Gaskets

We carry the largest stock of Imported Copper Gaskets in the United States. All sizes, from one-half to three and one-half inches inside measurement, in stock. Interesting prices quoted to the trade upon request.

## Pirelli Cable

Imported high and low-tension cable, made by Pirelli & Cie., Milan, the largest and oldest cable factory in the world. Used by all the leading Auto Manufacturers in America and Europe, and giving universal satisfaction. Made in five sizes.

## Goggles

We carry the largest stock of Imported Goggles in the United States, and are prepared to offer the latest and newest designs. Special prices to the trade.

## Annunciators

A cleverly designed instrument for communicating to chauffeur from limousine of car. Directions appear very distinctly day or night. Price, with round dial.....\$75.00 Price, with oblong dial..... 50.00

## Ceiling Lights

A large assortment of imported ceiling lights of various designs carried in stock. We have exercised great care in selecting them, and feel confident that our designs are the foremost on the market.

## English Compound Pumps

Reduce Your Tire Bills. Pumps your tire up in less time and with less exertion than any other pump made. Air is forced into the tire on both the up and downstroke. Pumps are equipped with gauges indicating amount of pressure being pumped into the tire. Price of Double Compound Pump, \$12.00. Price of Triple Expansion Pump, \$18.00.

Triple Pump

## Socket Wrenches

Imported telescoping socket wrenches. Their novel construction especially adapts them for automobile use. With them otherwise inaccessible parts can be easily reached. Set C consists of four pieces and lever handle.....\$5.00 Set D consists of five pieces and lever handle..... 6.00

# The MOTOR CAR EQUIPMENT CO.

# OF AUTOMOBILE SPECIALTIES

## The Latest French Siren

This is the new type of the straight siren horn. Has a 10-inch bell and a large turbine, producing a powerful sound, that can be heard for very long distances. Operates by engine flywheel only.  
Used all over Europe, and is very popular.  
Price, complete .....\$50.00

## The Argos Mirror

This mirror allows the chauffeur to see at a glance the movements of all moving vehicles behind him, allowing him to turn, back and reverse without jeopardizing the occupants of the machine.

It is a special plate glass mirror bound solidly in brass, with a brass hood on top to protect the face of the mirror from rain. Has a ball and socket joint, so that it may be moved in any position.

The mirror is slightly concave, and gives an extraordinarily wide range of vision behind. Nothing can occur behind the driver which he cannot readily observe.

Price .....\$20.00

## Spark Plugs—Bougie A. V

An indestructible plug, which can be easily taken apart. Presents only metallic surfaces while in contact with explosion.  
No. 159. Price, metric or half-inch thread .....\$2.00

## Speaking Tubes

For use in limousine cars. Constructed of polished hammered brass or gun-metal and fitted with silk covered tube and bulb. Mouthpiece being made of buck horn, which gives it a dainty appearance.

By pressing bulb a sound is produced that will attract the driver's attention.  
Price .....\$20.00

## Spark Plug—Genuine De Dion

The largest selling imported plug in the world. Made of selected material. High class in every respect. Made in metric thread only.  
No. 149. Price.....\$1.50

## Ceiling Light Switch

For use in connection with ceiling lights these imported switches are the best. Finished in mahogany or bone with nickel-plated snap lever.

Height, 1" diameter, 1 1/4".  
Price:  
Mahogany..\$1.00  
Bone ..... 1.50

## Spark Plug—French Mica

Amber Mica Plug. Composition platinum joints ensure positive spark. Suitable for Auto or Motor Cycle.  
No. 160. Price, 1/2" or metric thread .....90c

## Valve Spring Remover

Designed to facilitate the removal and replacement of Valve Springs, and is fitted with three fulcrum screws of various lengths, so as to fit all makes of engines.  
Price, including three screws.....\$1.50

## Steering Pillar Lamp

When fastened to the steering pillar of a motor car this lamp enables the driver to direct a powerful beam of light to any part of the dash board, and to keep under careful observation while driving at night his lubricators, water circulation gauge, speed indicator, watch, or any other device which may be on the dash.

Has a spring universal joint, which keeps the lamp perfectly tight in any position, yet allows it to be moved with the greatest of ease.

Lamp can be operated by storage battery.  
Price .....\$6.00

## RUSHMORE CONVENIENCE

Section of Rushmore Headlight with  
Back Cap Removed

is not as vital a consideration to the purchaser as Rushmore efficiency, but it is the best of its sort, nevertheless. If you have the ill luck to hit something, and the lamps need repairing, you will appreciate the fact that Rushmore Lights are put together throughout with bolts and rivets. No solder is used except to hold the nuts from unscrewing.

To replace the lens mirror, remove the back cap, as shown in the illustration, by unscrewing six bolts; then unscrew the six back bolts which hold the lens retaining ring.

To replace broken strips in the front glass, unscrew the bolts holding the front retaining ring.

The ventilator is bolted in place. The burner is bolted and is adjustable for accurate focusing. Other parts are fitted accurately together and riveted. The rivets are not a bluff to conceal the use of solder, as is sometimes done in lamps made up cheaply from stock too thin to hold rivets. No tinsmithing is needed for any sort of repair.

Have lightest weight, guaranteed strength, usable broad base or folded narrow base, latest construction, foot power. Why get down in the dirt? Ask your dealer or we deliver in U. S. or Canada.

**Jersey Brake Co.,** 3 Greene St., Newark, N. J.

# Prest-O-Lite

Danger, worry, trouble and care are alike unknown to the motorist who enjoys the comfort and convenience of Prest-O-Lite.

**"CONDENSED SUNSHINE"**

If your car isn't equipped with Prest-O-Lite, you may know that there are 35,000 people in this country to-day who are getting more pleasure out of autoing than you are.

But you can quickly and easily equip your car with dependable Prest-O-Lite and make night travel a pleasure instead of a course of harrowing anxiety. We now have

**1600 PREST-O-LITE EXCHANGE STATIONS**

In every part of the country there are Prest-O-Lite stations where you can have a Prest-O-Lite Tank put on your car, or can exchange an empty tank for a filled one in a moment's time. When the tank is on, all you have to do is turn a valve to operate it. There's no cleaning, tinkering or fussing with dirty carbide generators for the motorist who uses Prest-O-Lite.

**CAUTION**—Unscrupulous imitators are trying to sell inferior tanks somewhat like the original Prest-O-Lite tank of three years ago. These tanks are not to be depended upon. You are cautioned to look for the name **PREST-O-LITE** on the tank you buy. The name "Prest-O-Lite" is there for your protection, and is a guaranty of dependable goods.

On request we will mail you the Free Prest O-Lite Booklet and direct you to the nearest Prest-O-Lite station.

**HAM'S LAMPS**  
Proved the best  
By a most Rigid test

You won't have to consider the lamp question long if you give Ham's "Cold Blast" Lamps a trial. They embody all the good features you could possibly expect in oil lamps, and more Style, Finish, Quality of material, Strength of construction and excellent burning qualities. They give an immense light and will not blow or jar out.

Ask the man who has used them and also write for one of our new catalogues. Address "Dept. B."

**C. T. Ham Mfg. Co.**  
Rochester, N. Y.

## THE BOWERS CARBURETER

*The Instrument of PERFECTION*

PERFECT CARBURETION can only be attained by using our PATENTED METHODS. It is useless to try to secure equal results in any other manner.

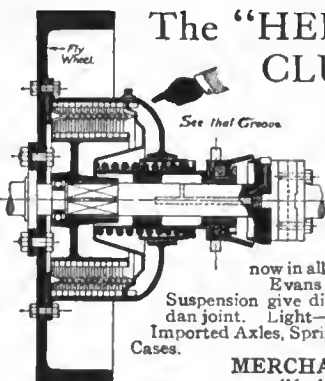

Take an ordinary carbureter, compare it with a dozen more, you will find some difference, but not in principle, and that principle is inherently WRONG. If all were made equally good they would all produce exactly same results. The BOWERS CARBURETER functions on correct practical principles, which have been secured by elaborate tests, giving more complete knowledge of this subject than ever possessed by others.

Send for our Catalog.  
It will interest you, and a trial carbureter convince, beyond all doubt.

## THE Complete Motorist

BY A. S. FILSON YOUNG

All about the automobile; how to select and run it; its mechanism and history. The absence of theory without sacrificing practical value makes this volume of special interest to the autoist who, though not mechanically inclined, wishes to know all about the subject treated. Written in a style entirely different from the average treatise about automobiles, yet complete and entertaining, so that to read it is a pleasure rather than a task. The matter is interspersed with comments that liven it up wonderfully while in no way detracting from the technical value of the work.

Size, 6 inches by 9 inches, 328 pages. Nicely bound in cloth, delivered free, \$3.50.

Address: **THE AUTOMOBILE**, Flatiron Building, New York.

# "TRIUMPH" GREASE

**NO WASTE—NO WEAR**

Works the same Winter and Summer, being unaffected by heat or cold.

Never runs out. Owing to its heavy body it stays where it is put and does not waste off like oil. Being heavy-bodied, it always leaves a layer of grease between the opposing surfaces, reducing friction to a minimum and saving wear. Its molecules are practically indestructible and it lasts in ACTUAL WORK from 50 to 100 per cent. longer than other lubricants, therefore is immensely cheaper. Send a trial order today! 10 lb. Can \$2.00. For sale by all dealers, or send order direct to

**The Perfection Grease Co., South Bend, Ind.**

## The Land of Lovely Dreams

WHERE THE KNOTTED NORTHERN NERVES MAY RELAX AND REST

WHY should one go to Tampa rather than the resorts on the other coast of Florida? Because the climate of the west coast is far more equable, less enervating, more beneficial to nerves and mind than any other. The climate of Tampa is dry and its tropical warmth is tempered agreeably by westerly breezes from the Gulf of Mexico. While

the glorious sunshine in the day time reminds one of the close proximity of the tropical Everglades, night brings with it refreshing coolness and fragrant dews, and with them comes, without fail, "Nature's sweet restorer, balmy sleep." Apply to agents of The Seaboard Air Line Railway, The Atlantic Coast Railway, Southern Railway, and their connecting lines.

*Booklet and Tariff sent on application.*

**\$1.75 PREPAID TO ANY ADDRESS IN THE U. S.**

**GIVE A CARE** to your gasoline pipe strainer, as nine times out of ten it is the secret of carburetor troubles. A little water or foreign substance in the gasoline will put your carburetor out of commission. Our strainer is a guarantee against such troubles. It is made from sheet brass, highly polished, and furnished with either 1/4 or 5/16 inch connections. The gasoline enters through the low connection, strains through a chamomil placed at an angle across the globe, and passes to the carburetor through the upper connection, cleansing the gasoline thoroughly. The foreign substance remains beneath the chamomil and may be drained through the petcock. Write to-day for catalog. Special prices to manufacturers and dealers in quantities.

**The Hatcher Auto-Parts Co.** 185 Viaduct CLEVELAND, OHIO

## Self Propelled Vehicles

BY J. R. ROMANS

An excellent book treating of the practical side of the construction and operation of automobiles with full information for the novice or the experienced operator. Tells what to do and how to do it. Describes in detail the mechanism of a modern car and explains the functions of each part. Forty-four chapters of good sound information for those interested in automobiles. This book contains 672 pages and over 500 interesting illustrations and diagrams.

Size, 5 3/4 inches by 8 1/2 inches. Printed on fine paper and substantially bound in cloth. Delivered, \$2.00.

Address: THE AUTOMOBILE, Flatiron Building, New York.

### Rock Island Automatic Swivel Vise

We make a size, this type, for automobiles. The base is fastened to the step or tool box at all times. The vise can be kept in the tool box and when needed is instantly ready for use. No screws, bolts, pins, etc.

Send for Catalogue.

Rock Island Tool Co., Rock Island, Ill.

### The Energy End

of the automobile should get the best attention—and that means the proper oil. Mobiloil is the only scientifically accurate lubricant for automobiles—because every make of engine requires its own kind of lubricant, and

## VACUUM MOBILOIL

in its various grades meets these requirements. Send for booklet which lists every make of automobile and tells just what grade of Mobiloil your automobile requires. Contains valuable pointers for motorists. It's free. Mobiloil comes in barrels and cans of varying capacities.

Manufactured by  
VACUUM OIL CO., Rochester, N. Y.

The Easy Pouring Can

## EASTERN GAS ENGINE DRY CELLS

Give more voltage, more amperage, more life, more uniformity and better efficiency than any other battery, and its recuperative power is the wonder and admiration of every user.

EASTERN BATTERY CONNECTOR  
POSITIVELY WON'T SHAKE LOOSE

Eastern Carbon Works

Carbon Place Jersey City, N. J.

### THE Jencick Motors

Suitable for Pleasure Cars and Heavy Duty Trucks, where reliability and efficiency are wanted.

H. P. 12 to 70, 2-4 and 6 cylinder, watercooled, four cycle, make and break and jump spark. Krupp chrome nickel steel. Parsons' manganese bronze base. Hess & Bright ball-bearings—simplicity of design and experienced workmanship. These are some of the Jencick features.

MOTORS BUILT BY NONE BUT SKILLED LABOR

and the above-mentioned materials, will have everlasting efficiency and durability. We will be pleased to mail catalogue on request.

JENCICK MOTOR MFG. CO., Port Chester, N. Y.

## English Speed Indicators

"Smith" Speed Indicators are worth the slightly higher price because they are:

- MORE ACCURATE and SENSITIVE** at all speeds on account of the hand workmanship and the 3-spring governor.
- MORE RELIABLE** because of the slow revolution of the driving shaft, and the use of friction drive instead of exposed cogs.
- MORE CONVENIENT**, because they are made both singly and in many combinations (see Type 5 above) with 8-day clocks, communicators, compasses, barometers, etc.

The attachment is universally adjustable.

# BREECH-BLOCK

## BETTER VALUE THAN ANY OTHER PLUG MADE

Insures cleanliness, freedom from the "fussed-up," uncomfortable condition consequent of working around a hot engine, and, best of all, insures comparative freedom from faulty ignition.

Eliminates Your Sparking-Plug Troubles

SAVES TIME, TOOLS, TEMPER and TROUBLE  
 No other Plug possesses so many distinct advantages of value and efficiency.

The Breech-Block enables the operator to open and clean the plug in four seconds

- One-sixth turn of the handle opens
- Entire porcelain is exposed for cleaning
- One twist makes instantly white
- Locks with the push of a finger
- Tight to 2,000 pounds
- No wrench to get, use or replace
- Terminal clips with each plug
- No thumb-nuts to loosen. No pliers
- Stuffing-nut chambered
- Plugs held by their handle in testing
- Not balanced on edge of your engine
- Soot-proof to the limit
- Unaffected by oil
- Chambered end protects porcelain
- Keeps porcelain fragments from cylinder
- Slightest piston movement cleans points
- Makes starting easy; fires first charge
- Big cars run slow on high gear
- Closely throttled; not a skip

INSIST ON HAVING THE "BREECH-BLOCK" PLUG  
 Every possible requirement completely satisfied

# Stevens-Duryea Six-Cylinder Automobiles

The wise automobile buyer will purchase a six-cylinder car if he desires a horse power of forty or over, or pays more than \$2,750. The six-cylinder car has so thoroughly demonstrated its great superiority over the high-powered Four that the latter type of car is being built by fewer manufacturers each succeeding year.

Six cylinders are absolutely necessary if you are to derive the maximum amount of pleasure in motoring.

It is obvious, however, that but few manufacturers are experienced builders of Sixes, inasmuch as the majority of manufacturers held back until they were forced to build Sixes. The Stevens-Duryea Company were the six-cylinder pioneers in America. The design of the Stevens-Duryea Big Six, which scored an instant and unqualified success, was being worked out a year before the first car was built in 1905. Hundreds of Stevens-Duryea Sixes were in use and giving satisfaction when manufacturers generally were starting to build Sixes.

The famous Stevens-Duryea Unit Power Plant and Three Point Support insure perfect alignment always, lighter weight and extreme simplicity and durability. Its six cylinders mean perfect control, quiet running and absence of vibration.

Don't purchase an experiment simply because it is a Six-cylinder car. Select a car that is a known quantity. Stevens-Duryea Sixes have been a known quantity since 1905.

- Model U—Light Six.....\$3,500
- Model U—Light Six Limousine.....4,500
- Model S—Big Six.....6,000
- Model R—Limousine.....3,300

Evidence Almost Beyond Belief of the Efficiency of the  
ELMORE IGNITION SYSTEM

Added to all the accumulated evidence of the past comes now a test so conclusive and sensational that it should interest every man who owns a car—whether it be an Elmore or not.

During the first week of December an Elmore Forty—the four-cylinder, two-cycle car—was driven 212 1-2 miles on a battery of six small vest-pocket flash lamp cells. Do you realize what that means?

These cells are about one inch in diameter and four inches long. Let us repeat again—one inch in diameter and four inches long. Not only did these miniature current producers supply the sparks for 212 1-2 miles, but they were drained down to 2-10 of an ampere.

When the test was stopped to enable the batteries to be exhibited at the Chicago show, the engine was still running on this small spark produced by 2-10 of an ampere of current—really but a small fraction of the amount of current necessary to operate the average four-cycle car.

Now don't you want to know more about an Elmore valveless, two-cycle engine—about an Elmore ignition system—about an Elmore car itself? Better consult the nearest agent—but write us for literature.

# CHRISTMAS JOY

## The whole year 'round

for  
users of

# SCHEBLER CARBURETER

It is successful Carburetion that makes automobiling pleasurable and practical.

Users of "SCHEBLER" Carbureters have both in fullest measure the whole year 'round.

### "SCHEBLER" CARBURETER

ALWAYS RELIABLE regardless of engine speeds or atmospheric conditions—a perfect and uniform mixture always and an increase in the power of your engine of 20 to 30 per cent.

The Manufacturer owes it to the Public and the Public owes it to themselves to insist on having the "SCHEBLER" CARBURETER on their cars. "Just-as-good" is but a tribute to "SCHEBLER" superiority and should be so understood.

# THOMAS

## *The E. R. Thomas Motor Company Presents Four Styles of Chassis and Nineteen Styles of Bodies*

**THOMAS 4-20 TOWN CAR.** Combines luxury with utility and necessity; designed particularly for city and suburban use in good or bad weather, for calling and shopping, for the theatre, for social functions and touring on good roads. This car is furnished with brougham, landaulet, cabriolet, limousine and doctor's car bodies. In Europe this style of car is the vogue, as it rapidly is becoming in America. Prices, \$3,000 to \$3,250.

**THOMAS 4-40 DETROIT.** A marvel of smooth and quiet running with a dash in operation and distinctive style in appearance that denotes the thoroughbred and fascinates the most critical. The 4-40 has been strengthened and improved where the wisdom of experience has suggested. It is especially designed to successfully eclipse, at a much lower price, shaft-driven cars of the highest price and class. It is equipped with runabout, tourabout, touring and limousine bodies. Prices, \$2,750 to \$3,750.

**THOMAS 4-60 FLYER.** The Old Reliable is smoother, snappier, faster, lighter, quieter and roomier than ever. It has been redesigned and refined until it has become one of the most beautiful and stylish cars to be seen. The mechanical changes are largely refinements, though the motor generates more power. A bearing between each cylinder is still one of its chief characteristics. It is equipped with runabout, tourabout, touring, landaulet and limousine bodies. Prices, \$4,500 to \$5,700.

**THOMAS 6-70 SPECIAL.** This is the climax of automobile construction, and is one of the most powerful and flexible cars made, retaining, as it does, the structural principles that have counted so much for reliability in the Thomas 4-60 Flyer. There is not a single experimental feature in its entire construction. For speed, smooth running on hills and bad roads, and for slow speed, all on the high gear, the 6-70 Special is not equalled. It is equipped with runabout, touring, landaulet and limousine bodies. Prices, \$6,000 to \$6,900.

BUFFALO, N. Y.

*"You  
Get  
What  
You  
Pay  
For."*

When we began the manufacturing of speed indicators we promised ourselves that quality should rule above all other considerations. That promise has never been broken.

We believed then, as we do now, that quality and honesty and fair dealing could be made to pay dividends. How well that belief has been borne out is best told by the fact that

## The Warner Auto-Meter

was on 70 per cent of the Glidden Tour 1907 contesting cars and on 60 per cent of the cars entered in the Glidden 1906 Tour.

That the Warner Magnetic principle of speed indication is the only one is proved by the fact that it has been adopted by the United States Government to show the velocity of the wind. Uncle Sam wants the best—a poor speed indicator is worse than none—he knows that he can't get a reliable one for less than the Warner price.

*Write for Complete Information.*

*Warner*

Winter Automobiling has a charm that is equalled  
by no other open air pastime, and with a

## JOHN BOYLE TRUNK

you are always ready for any emergency, regardless of weather changes—rain, sleet, cold winds or snow, or stop-overs en tour

With a **John Boyle Trunk** you can carry all requirements of clothing and other necessities for your family and self in one roomy, safe, sure—under lock and key—water-proof and dust-proof trunk, strapped out of your way at the rear of the car. Easily opened en route. At your destination unstrap from car and send into your rooms. Of inestimable convenience—gives pleasure, comfort and satisfaction to all tours and a finer appearance to your car. John Boyle & Co.'s trunks have a style and quality exclusively their own—none of the imitations approach them in any way, and their quality of material and construction makes them almost everlasting.

*Write for Style Book and Prices for the various makes of cars*

# It is the Practical Things that Count

In the recent three-day 600-mile Reliability Run of the Chicago Motor Club a

# Rambler

stock car with no special preparation or equipment made every control on time without an instant's delay or attention and finished in perfect condition.

A hypertechnical committee deprived us of a perfect score on account of a damaged tail lamp and loosened speedometer bracket, but the fact remains that this car underwent the most severe test ever devised without a seal being broken or the tool bag opened, and was at the finish in the same perfect condition as at the start.

Thus was the Rambler again proven

## THE CAR OF STEADY SERVICE

If you want a car that is **RIGHT** at a price that is **REASONABLE** with the backing of one of the most powerful companies in the industry, see the Rambler line for 1908.

Two touring cars and a roadster at \$1,400 and \$2,250.

Catalog 34 upon request.

## The Model Line for 1908

**RUNABOUT CAR No. 11**  
 Motor—Double opposed, 5 x 7, 24-h.p. Wheelbase—100".  
 Tires—32" x 3 1/4". Body—Tilting type. Weight—1,650  
 pounds. Price—\$1,150.

A speedier car and better hill climber than any car manufactured by any one in which a double opposed motor is used.

**FIVE PASSENGER CAR NO. 12**  
 Motor—Double opposed, 5 x 7, 24-h.p. Wheelbase—100".  
 Tires—32" x 3 1/4". Body—Tilting. Tonneau—Detachable.  
 Width of rear seat inside of upholstery—50". Depth—  
 18". Height—24". Length of tonneau floor—30". Full  
 specifications of this car will interest you.

**FIVE PASSENGER CAR No. 14**  
 Motor—Double opposed, 5 x 7, 24-h.p. Wheelbase—104".  
 Tires—32" x 3 1/4". Body—Tilting. Tonneau—Detachable.  
 Pressed steel construction throughout. Large, roomy, and  
 a beautifully designed body. Easily in a class by itself,  
 when it comes to easy riding, because of the long wheel-  
 base and full elliptic springs.

**FIVE TO SEVEN PASSENGER CAR No. 15**  
 Motor—4-cylinder, 5 x 5 1/2, 50-h.p. Transmission—Slid-  
 ing gear, progressive type. Clutch—3 disc, metallic, with  
 cork insert. Wheelbase—118 1/2". Wheels—1 1/2" spoke.  
 Tires—36 x 4 1/4", rear; 36 x 4" front. Front springs—42"  
 long; rear—54". Weight—2,900 pounds. Price—\$3,500.

**SEVEN PASSENGER CAR No. 16**  
 Motor—4-cylinder, 5 x 5 1/2, 50-h.p. Transmission—Slid-  
 ing gear, selective type. Clutch—Multiple disc. Wheel-  
 base—122". Wheels—1 3/8" spoke. Tires—Rear, 36 x 4 1/4";  
 front, 36 x 4". Springs—Front, 42"; rear, 54". Weight—  
 3,000 pounds. Price—\$4,000.

For full specifications of above cars write for advance catalog No. 10.

# THE INCOMPARABLE WHITE THE CAR FOR SERVICE

## Exclusive Features of the White Limousine.

The exclusive White quality of absolute noiselessness of operation is of particular advantage in a limousine, because in a car with a closed body any noise made by the mechanism is even more noticeable and annoying than in an open vehicle.

Another exclusive White quality—namely—genuine flexibility of control, permits of the machine being guided safely and speedily through the crowded city streets. The speed of the White may be accommodated to the exigencies of street traffic without any changing of gears, jerky starts or the embarrassing and sometimes dangerous “stalling” of the engine.

As regards graceful lines and luxuriousness of equipment and finish, the White limousine must be seen to be appreciated.

---

Let us show you the unequalled luxury and comfort  
of the White limousine

---

**THE WHITE COMPANY**  
**CLEVELAND, OHIO**

## Don't waste money and power with a heavy automobile

It takes gasoline and power to move weight. So every pound of weight that you don't need, wastes your fuel (money) and keeps your engine from giving the greatest speed and hill-climbing

ability. Excess weight bears down on tires and wears them out—*expense*. The heavy water-cooled automobile has more parts to get out of order—more *expense*.

The light-weight, air-cooled Franklin weighs a great deal less than any other automobile of its power. No unnecessary weight to cut down speed and ability on hard roads and hills. The smallest cost for fuel and tires. And very little cost for maintenance and repairs.

Write for the Franklin catalogue.

H. H. FRANKLIN MFG. CO., Syracuse, N. Y.

Member Associated Licensed Automobile Manufacturers

Type D. Five-Passenger Touring Car. 28 horsepower, \$2,850

# WINTON

The six-cylinder Winton Six-Teen-Six is **jerkless, joltless, vibrationless.** Does more and prettier work than any four you ever saw. Develops driving power at slow motor speed, reserving an abundance of high motor speed for a dashing spin or a superb hill climb on the high. Starts from the seat on compressed air. Creeps through crowded traffic on the high, ever ready to dash through the first opening in response to throttle. Avoids gear shifting. Goes the route **like coasting down hill.**

One demonstration is convincing that the Six-Teen-Six is precisely the car for the man who wants the best there is.

## THE AUTOMOBILE TRADE DIRECTORY

¶ Its sole purpose is to tell the buyer who makes the thing he wants, and the arrangement of our classified lists presents the advertiser's name and announcement to the purchaser just when the latter wants the identical thing advertised.

¶ The Directory is constantly referred to by Managers, Mechanical Engineers, Superintendents, Purchasing Agents, the men who specify and buy parts and material for the construction of cars, and by Dealers, Garages, Supply Jobbers, and the entire trade.

Could advertising be placed more exactly where it should go?

### The Automobile Trade Directory Mailing List

comprising every Garage, Electric Charging Station, Salesroom, Repair Shop, Supply House and the purchasing agents, mechanical engineers, etc., of automobile manufacturing concerns in the United States and Canada.

¶ This list enables our advertisers to "follow up" their advertising in The Automobile Trade Directory by direct communication with buyers through letters, circulars, etc.

¶ Our new Mailing List (now on the press) has been thoroughly revised and corrected to date, and is by far the most complete and accurate in existence. Monthly revisions and supplements will be furnished to keep it so.

¶ By this effective publicity and direct communication you concentrate your selling effort to the definite field you wish to reach and make it possible to talk to more active buyers for less money than in any other way.

## The Last Word in GREAT ARROW Car Construction is LUXURY.

The four-cylinder GREAT ARROW was and still is a good car as far as efficiency in service is concerned. The six-cylinder adds a touch of luxury, due to ABSENCE OF VIBRATION, which sums up in one word the chief argument in favor of the six-cylinder GREAT ARROW.

THERE ARE MANY MINOR ADVANTAGES, such as lighter weight of certain parts, ease in starting, possibility of running in traffic on a high gear and other things that will appear to the experienced motorist, but after all, THE ONE GREAT ARGUMENT IN FAVOR OF SIX CYLINDERS IS COMFORT.

A motor car is a pleasure vehicle, and the more comfortable we can make it, the more nearly it becomes the ideal pleasure vehicle, and comfort, luxury, the sensation of gliding rather than being propelled by machinery, are the results attained in the six-cylinder GREAT ARROW.

HERE ARE THE  
1908 TOURING CARS

4-cylinder Great Arrow, 30 H.P., Price, \$4,000  
4-cylinder Great Arrow, 40 H.P., Price, \$5,000  
6-cylinder Great Arrow, 40 H.P., Price, \$5,500  
6-cylinder Great Arrow, 60 H.P., Price, \$6,500
